Some good news

let me **Google** that for you

Google Search

I'm Feeling Lucky

Focus on the concepts, not the details... and google everything else

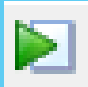

Some more good news

Script basics

A script is a list of commands that are executed almost as if you were typing them into the command window, line by line

Action:

- Open a new script
- create a variable, `x`, which is a list of 5 numbers
- save it as `matlab_basics`
- Run script 

Script basics

- ‘%’ For bits you don’t want to be run (titles, notes etc)

Add me

Use these liberally!

- ‘;’ To stop line printing in command window

Add me

- `save('filename','variables')`

Add me

```
save('test.mat', 'x')
```

- F5-run script, F9-run highlighted bit

Run save

Comparison operators

- Operators that tell us how two variables relate
- 1 = true, 0 = false
- Can run on lists, 2D data and... any dimension of data

Type `2>3` and run

Type and run:
`a = randi(100, 10)`
`a >= 50`

Operator	Meaning
<code>==</code>	Is equal to
<code>~=</code>	Is not equal to
<code><</code>	Is less than
<code><=</code>	Is less than or equal to
<code>></code>	Is greater than
<code>>=</code>	Is greater than or equal to

Combining Operators

Operator	Meaning
~	NOT/OPPOSITE
&	AND (need true AND true)
	OR (need true OR true)
==	Is equal to
~=	Is not equal to
<	Is less than
<=	Is less than or equal to
>	Is greater than
>=	Is greater than or equal to

$y = 5$

$y > 3 \mid y \neq 5$

True or False

= 1

What would be the answer to:

$x = 8$

$y = 9$

$\sim(\sim(x < 3)) \& \sim(y > 14 \mid y > 10)$

Conditional statements

- Comparison operators $<$, $>$, $<=$, $>=$, $==$, $\sim=$
- Combining operators and ($\&$), or ($|$) and not(\sim)
- Conditional statements:
 - if, elseif, else

If

```
if this is true
    %Do whatever is in the middle
elseif this is true
    %Do whatever is in the middle
else
    %Do whatever is in the middle if
    neither above are true
end
```

If

```
a = 33;  
  
if a < 30  
    disp('small')  
elseif a < 80  
    disp('medium')  
else  
    disp('large')  
end
```

Create an If statement

- $X = 10$, $\text{minVal} = 2$, $\text{maxVal} = 6$
- Write a script to print out (using 'disp'):
 - a) 'Value within range' if x is within or equal to the range parameters
 - b) 'Value exceeds maximum value' if it's larger than maxVal
 - c) 'Value is below minimum value' if it's smaller than minVal
 - d) Test different x to check it's working

Answer

```
x = 10;  
minVal = 2;  
maxVal = 6;  
  
if (x >= minVal) & (x <= maxVal)  
    disp('Value within specified range.')elseif (x > maxVal)  
    disp('Value exceeds maximum value.')else  
    disp('Value is below minimum value.')end
```

Repetitions: For loops

```
%General structure:  
for index = values  
    %Do whatever is in the middle  
end
```

```
%Example:  
data = [1 : 100];  
n = length(data);  
result = 0;  
for k = 1 : n  
    result = result + data(k);  
end  
result_2 = result/n
```

Use variable names that describe what it is

Create a for loop

- Define an array with 5 numbers between 0 to 10 as you like. Each number represents the score of a subject in a test.
- For each subject, apply a correcting factor on the grades. Create a new variable which will contain the revised grades. The factor should be: $x = x * 1.2$.
- If the revised grade is larger than 10, set it to 10.
- In the workspace, make sure you can see the two variables and that their values make sense.

Answer

```
score = [1, 5, 7, 9, 8];  
n = length(score);  
for ind = 1:n  
    revised_score(ind) = score(ind)*1.2;  
    if revised_score(ind) > 10  
        revised_score(ind) = 10;  
    end  
end
```

Initialize arrays rather than growing with each loop
E.g. use `revised_scores= zeros(size(score))`

Functions

- You can run a script from the command line or from another script
 - Put your for loop in a new script and save as `my_for_loop`
 - Run your script by typing `my_for_loop` into the command window
- Want more flexibility? Functions...
- Like a script but you pass input values and return output values

Functions

```
function [outputs] = function_name(inputs)

%Put your script in here

end
```

Save the script as 'function_name'

Create a function

- Want to revise score with any given factor (variable called 'correct_factor'), not just *1.2
- Turn your for loop script into a function that takes inputs: 'scores' and 'correct_factor' and gives the revised scores as an output
- Run from the command line with a few different inputs to test
