

Package ‘MBESS’

May 9, 2011

Title MBESS

Version 3.2.1

Date 2011-5-5

Author Ken Kelley and Keke Lai

Maintainer Keke Lai <Lai.15@ND.Edu>

Depends R (>= 2.6.0)

Suggests MASS, sem, gsl, boot, nlme

Description MBESS implements methods that are especially useful to researchers working within the behavioral, educational, and social sciences (both substantive researchers and methodologists), Many of the methods contained within MBESS are applicable to quantitative research in general,

aipe.smd	<i>Sample size planning for the standardized mean different from the accuracy in parameter estimation approach</i>
----------	--

Description

A set of functions that `ss.aipe.smd` calls upon to calculate the appropriate sample size for the standardized mean difference such that the expected value of the confidence interval is sufficiently narrow.

Usage

```

ss.aipe.smd.full(delta, conf.level, width, ...)
ss.aipe.smd.lower(delta, conf.level, width, ...)
ss.aipe.smd.upper(delta, conf.level, width, ...)

```

Arguments

delta	the population value of the standardized mean difference
conf.level	the desired degree of confidence (i.e., 1-Type I error rate)
width	desired width of the specified (i.e., Lower, Upper, Full) region of the confidence interval
...	specify additional parameters in functions these functions call upon

Value

n	The necessary sample size per group in order to satisfy the specified goals.
---	---

Warning

The returned value is the sample size **per group**. Currently only `ss.aipe.smd.full` returns the exact value. However, `ss.aipe.smd.lower` and `ss.aipe.smd.upper` provide approximate sample size values.

Note

The function `ss.aipe.smd` is the function users should generally use. The function `ss.aipe.smd` calls upon these functions as needed. They can be thought of loosely as internal MBESS functions.

ss.aipe.smd

ancova.random.data *Generate random data for an ANCOVA model*

Description

Generate random data for a simple (one-response-one-covariate) ANCOVA model considering the covariate as random. Data can be generated in the contexts of both randomized design (same population covariate mean across groups) and non-randomized design (different population covariate means across groups).

Usage

```
ancova.random.data(mu.y, mu.x, sigma.y, sigma.x, rho, J,
n, randomized = TRUE)
```

Arguments

mu.y	a vector of the population group means of the response variable
mu.x	the population mean of the covariate (in the randomized design context), or a vector of the population group means of the covariate (in the non-randomized design context)
sigma.y	the population standard deviation of the response variable
sigma.x	the population standard deviation of the covariate
rho	the population correlation coefficient between the response and the covariate
J	the number of groups
n	the number of sample size per group
randomized	a logical statement of whether randomized design is used

Details

This function uses multivariate normal distribution to generate the random data; the covariate is considered as random in the model. This function uses `mvrnorm` in the `MASS` package as an internal function, and thus it requires the `MASS` package be installed first.

This function assumes homogeneous covariance matrix among groups, in both the randomized design and non-randomized design contexts.

Value

This function returns an n by $J*2$ matrix, where n and J are what are defined in the argument. The first J columns of the matrix contains the random data for the response, and the second J columns of the matrix contains the random data for the covariate.

Author(s)

Keke Lai <Lai.15@ND.edu>

Examples

```
random.data <- ancova.random.data(mu.y=c(3,5), mu.x=10, sigma.y=1,
sigma.x=2, rho=.8, J=2, n=20)
```

CFA.1

One-factor confirmatory factor analysis model

Description

Returns the MLE estimates and the estimated asymptotic covariance matrix of parameter estimates for one-factor confirmatory factor analysis model

Usage

```
CFA.1(S, N, equal.loading = FALSE, equal.error = FALSE)
```

Arguments

<code>S</code>	covariance matrix of the indicators
<code>N</code>	total sample size
<code>equal.loading</code>	logical statement indicating whether the path coefficients are the same
<code>equal.error</code>	logical statement indicating whether the manifest variables have the same error variances

Value

<code>Model</code>	the factor analysis model specified by the user
<code>Factor.Loadings</code>	factor loadings
<code>Indicator.var</code>	the error variances of the indicator variables
<code>Parameter.cov</code>	the covariance matrix of the parameters

```

ci.c

Confidence interval for a contrast in a fixed effects ANOVA

Description

Function to calculate the exact confidence interval for a contrast in a fixed effects analysis of variance context.

Usage

```
ci.c(means = NULL, error.variance = NULL, c.weights = NULL, n = NULL,
N = NULL, Psi = NULL, conf.level = 0.95, alpha.lower = NULL,
alpha.upper = NULL, df.error = NULL, ...)
```

Arguments

means	a vector of the group means or the means of the particular level of the effect (for fixed effect designs)
error.variance	the common variance of the error (i.e., the mean square error)
c.weights	the contrast weights (the sum of the contrast weights should be zero)

<code>n</code>	sample sizes per group or level of the particular factor (if length 1 it is assumed that the per group/level sample sizes are equal)
<code>N</code>	total sample size
<code>Psi</code>	the (unstandardized) contrast effect, obtained by multiplying the j th mean by the j th contrast weight (this is the unstandardized effect)
<code>conf.level</code>	confidence interval coverage (i.e., 1- Type I error rate); default is .95
<code>alpha.lower</code>	Type I error for the lower confidence limit
<code>alpha.upper</code>	Type I error for the upper confidence limit
<code>df.error</code>	the degrees of freedom for the error. In one-way designs, this is simply N -length (means) and need not be specified; it must be specified if the design has multiple factors.
<code>...</code>	allows one to potentially include parameter values for inner functions

Value

Returns the confidence limits for the contrast:

<code>Lower.Conf.Limit.Contrast</code>	The lower confidence limit for the contrast effect
<code>Contrast</code>	the value of the estimated unstandardized contrast effect
<code>Upper.Conf.Limit.Contrast</code>	The upper confidence limit for the contrast effect

Note

Be sure to use the error variance and not its square root (i.e., the standard deviation of the errors).

Examples

```

ci.c(means=c(2, 4, 9, 13), error.variance=1, c.weights=c(1, -1, -1, 1),
n=c(3, 3, 3, 3), N=12, conf.level=.95)

ci.c(means=c(2, 4, 9, 13), error.variance=1, c.weights=c(1, -1, -1, 1),
n=c(3, 3, 3, 3), N=12, conf.level=.95)

ci.c(means=c(1.6, 0), error.variance=1, c.weights=c(1, -1), n=c(10, 10),
N=20, conf.level=.95)

# An example given by Maxwell and Delaney (2004, pp. 155--171) :
# 24 subjects of mild hypertensives are assigned to one of four treatments: drug
# therapy, biofeedback, dietary modification, and a treatment combining all the
# three previous treatments. Subjects' blood pressure is measured two weeks
# after the termination of treatment. Now we want to form a 95% level
# confidence interval for the difference in blood pressure between subjects
# received drug treatment and those received biofeedback treatment

## Drug group's mean = 94; group size=4
## Biofeedback group's mean = 91; group size=6
## Diet group's mean = 92; group size=5
## Combination group's mean = 83; group size=5
## Mean Square Within (i.e., 'error.variance') = 67.375

ci.c(means=c(94, 91, 92, 83), error.variance=67.375, c.weights=c(1, -1, 0, 0),
n=c(4, 6, 5, 5), N=20, conf.level=.95)

```

ci.c.ancova

Confidence Interval for an (unstandardized) contrast in ANCOVA with one covariate

Description

To calculate the confidence interval for an unstandardized contrast in the one-covariate ANCOVA.

Usage

```

ci.c.ancova(Psi, means, error.var.ancova = NULL, c.weights, n,
x.bar, SSwithin.x, conf.level = 0.95, ...)

```

Arguments

Psi	the unstandardized contrast of adjusted means
means	the vector that contains the adjusted mean of each group
error.var.ancova	the error variance obtained from the ANCOVA summary table; i.e., mean square within in the ANCOVA table

<code>c.weights</code>	the contrast weights
<code>n</code>	either a single number that indicates the sample size per group, or a vector that contains the sample size of each group
<code>x.bar</code>	a vector that contains the group means of the covariate
<code>SSwithin.x</code>	the sum of squares within groups obtained from the summary table for ANOVA on the covariate
<code>conf.level</code>	the desired confidence interval coverage, (i.e., 1 - Type I error rate)
<code>...</code>	allows one to potentially include parameter values for inner functions

Value

<code>lower.limit</code>	the lower confidence limit of the (unstandardized) ANCOVA contrast
<code>upper.limit</code>	the upper confidence limit of the (unstandardized) ANCOVA contrast

Note

Be sure to use the error variance and not its square root (i.e., the standard deviation of the errors).

If `n` receives a single number, that number is considered as the sample size per group. If `n` receives a vector, the vector is considered as the sample size of each group.

Be sure to use fractions not the integers to specify `c.weights`. For example, in an ANCOVA of four groups, if the user wants to compare the mean of group 1 and 2 with the mean of group 3 and 4, `c.weights` should be specified as `c(0.5, 0.5, -0.5, -0.5)` rather than `c(1, 1, -1, -1)`. Make sure the sum of the contrast weights are zero.

Examples

```
# Maxwell & Delaney (2004, pp. 428-468) offer an example that 30 depressive
# individuals are randomly assigned to three groups, 10 in each, and ANCOVA
# is performed on the posttest scores using the participants' pretest
# scores as the covariate. The means of pretest scores of group 1 to 3 are
# 17, 17.7, and 17.4, respectively, and the adjusted means of groups 1 to 3
# are 7.5, 12, and 14, respectively. The error variance in ANCOVA is 29,
# and the sum of squares within groups from ANOVA on the covariate is
```

```
# 313.37.

# To obtained the confidence interval for adjusted mean of group 1 versus
# group 2:
ci.c.ancova(means=c(7.5, 12, 14), error.var.ancova=29, c.weights=c(1, -1, 0),
n=10, x.bar=c(17, 17.7, 17.4), SSwithin.x=313.37)
```

ci.cv

Confidence interval for the coefficient of variation

Description

Function to calculate the confidence interval for the population coefficient of variation using the noncentral t -distribution.

Usage

```
ci.cv(cv=NULL, mean = NULL, sd = NULL, n = NULL, data = NULL,
conf.level = 0.95, alpha.lower = NULL, alpha.upper = NULL, ...)
```

Arguments

cv	coefficient of variation
mean	sample mean
sd	sample standard deviation (square root of the unbiased estimate of the variance)
n	sample size
data	vector of data for which the confidence interval for the coefficient of variation is to be calculated
conf.level	desired confidence level (1-Type I error rate)
alpha.lower	the proportion of values beyond the lower limit of the confidence interval (cannot be used with conf.level).
alpha.upper	the proportion of values beyond the upper limit of the confidence interval (cannot be used with conf.level).
...	allows one to potentially include parameter values for inner functions

Details

Uses the noncentral t -distribution to calculate the confidence interval for the population coefficient of variation.

Value

Lower.Limit.CofV	Lower confidence interval limit
Prob.Less.Lower	Proportion of the distribution beyond Lower.Limit.CofV
Upper.Limit.CofV	Upper confidence interval limit
Prob.Greater.Upper	Proportion of the distribution beyond Upper.Limit.CofV
C.of.V	Observed coefficient of variation

Examples

```
set.seed(113)
N <- 15
X <- rnorm(N, 5, 1)
mean.X <- mean(X)
sd.X <- var(X)^.5

ci.cv(mean=mean.X, sd=sd.X, n=N, alpha.lower=.025, alpha.upper=.025,
conf.level=NULL)
ci.cv(data=X, conf.level=.95)
ci.cv(cv=sd.X/mean.X, n=N, conf.level=.95)
```

 ci.pvaf

Confidence Interval for the Proportion of Variance Accounted for (in the dependent variable by knowing the levels of the factor)

Description

Function to obtain the exact confidence limits for the proportion of variance of the dependent variable accounted for by knowing the levels of the factor (or the grouping factor in a single factor design) group status in a fixed factor analysis of variance.

Usage

```
ci.pvaf(F.value = NULL, df.1 = NULL, df.2 = NULL, N = NULL,
        conf.level = 0.95, alpha.lower = NULL, alpha.upper = NULL, ...)
```

Arguments

<code>F.value</code>	observed F -value from fixed effects analysis of variance
<code>df.1</code>	numerator degrees of freedom
<code>df.2</code>	denominator degrees of freedom
<code>N</code>	sample size
<code>conf.level</code>	confidence interval coverage (i.e., 1-Type I error rate); default is .95
<code>alpha.lower</code>	Type I error for the lower confidence limit
<code>alpha.upper</code>	Type I error for the upper confidence limit
<code>...</code>	allows one to potentially include parameter values for inner functions

Details

The confidence level must be specified in one of following two ways: using confidence interval coverage (`conf.level`), or lower and upper confidence limits (`alpha.lower` and `alpha.upper`).

This function uses the confidence interval transformation principle (Steiger, 2004) to transform the confidence limits for the noncentrality parameter to the confidence limits for the population proportion of variance accounted for by knowing the group status. The confidence interval for the noncentral F parameter can be obtained from the function `conf.limits.ncf` in MBESS, which is used within this function.

Value

Returns the exact confidence interval for the proportion of variance of the dependent variable accounted for by knowing group status in a fixed factor analysis of variance.

`Lower.Limit.Proportion.of.Variance.Accounted.for`

The lower confidence limit for the proportion of variance accounted for in the deviation by group status.

```
Upper.Limit.Proportion.of.Variance.Accounted.for
```

The upper confidence limit for the proportion of variance accounted for in the deviation by group status.

Note

This function can be used for single or factorial ANOVA designs.

ci.pvaf(F.value=11.221, df.1=4, df.2=50, N=55, alpha.lower=0, alpha.upper=.05)
```

```
ci.R
```

Confidence interval for the multiple correlation coefficient

Description

Function to obtain the exact confidence interval for the multiple correlation coefficient when predictors are random (the default) or fixed.

Usage

```
ci.R(R = NULL, df.1 = NULL, df.2 = NULL, conf.level = 0.95,
     Random.Predictors = TRUE, Random.Regressors, F.value = NULL,
     N = NULL, K=NULL, alpha.lower = NULL, alpha.upper = NULL, ...)
```

Arguments

R	multiple correlation coefficient
df.1	numerator degrees of freedom
df.2	denominator degrees of freedom
conf.level	confidence interval coverage (i.e., 1- Type I error rate); default is .95
Random.Predictors	whether or not the predictor variables are random or fixed (random is default)
Random.Regressors	an alias for Random.Predictors; Random.Regressors overrides Random.Predictors
F.value	obtained <i>F</i> -value
N	sample size
K	number of predictors
alpha.lower	Type I error for the lower confidence limit
alpha.upper	Type I error for the upper confidence limit
...	allows one to potentially include parameter values for inner functions

Details

This function is based on the function `ci.R2` in MBESS package.

This function can be used with random predictor variables (`Random.Predictors=TRUE`) or when predictor variables are fixed (`Random.Predictors=FALSE`). In most applications in the behavioral, educational, and social sciences predictor variables are random, which is the default for this function.

For random predictors, the function implements the procedure of Lee (1971), which was implemented by Algina and Olejnik (2000; specifically in their `ci.smcc.bisec.sas` SAS script). When `Random.Predictors=TRUE`, the function implements code that is in part based on the Algina and Olejnik (2000) SAS script.

When `Random.Predictors=FALSE`, and thus the predictors are planned and thus fixed in hypothetical replications of the study, the confidence limits are based on a noncentral *F*-distribution (see `conf.limits.ncf`).

Value

Returns the confidence limits of the multiple correlation coefficient:

Lower.Conf.Limit.R	lower limit of the confidence interval around the population multiple correlation coefficient
--------------------	---

`Prob.Less.Lower`
 proportion of the distribution less than `Lower.Conf.Limit.R`
`Upper.Conf.Limit.R`
 upper limit of the confidence interval around the population multiple correlation coefficient
`Prob.Greater.Upper`
 proportion of the distribution greater than `Lower.Conf.Limit.R`

`ci.R2`

Confidence intervals for the squared multiple correlation coefficient

Description

A function to calculate the exact confidence interval for the multiple correlation coefficient.

Usage

```
ci.R2(R2 = NULL, df.1 = NULL, df.2 = NULL, conf.level = .95,
      Random.Predictors=TRUE, Random.Regressors, F.value = NULL, N = NULL,
      p = NULL, K, alpha.lower = NULL, alpha.upper = NULL, tol = 1e-09)
```

Arguments

R2	multiple correlation coefficient
df.1	numerator degrees of freedom
df.2	denominator degrees of freedom
conf.level	confidence interval coverage; 1-Type I error rate
Random.Predictors	whether or not the predictor variables are random or fixed (random is default)
Random.Regressors	an alias for Random.Predictors; Random.Regressors overrides Random.Predictors
F.value	obtained F-value
N	sample size
p	number of predictors
K	alias for p, the number of predictors
alpha.lower	Type I error for the lower confidence limit
alpha.upper	Type I error for the upper confidence limit
tol	tolerance for iterative convergence

Details

This function can be used with random predictor variables (`Random.Predictors=TRUE`) or when predictor variables are fixed (`Random.Predictors=FALSE`). In most applications in the *behavioral, educational, and social sciences* predictor variables are random, which is the default in this function.

For random predictors, the function implements the procedure of Lee (1971), which was implemented by Algina and Olejnik (2000; specifically in their *ci.smcc.bisec.sas* SAS script). When `Random.Predictors=TRUE`, the function implements code that is in part based on the Algina and Olejnik (2000) SAS script.

When `Random.Predictors=FALSE`, and thus the predictors are planned and thus fixed in hypothetical replications of the study, the confidence limits are based on a noncentral F-distribution (see `conf.limits.ncf`).

Value

Lower.Conf.Limit.R2	upper limit of the confidence interval around the population multiple correlation coefficient
Prob.Less.Lower	proportion of the distribution less than Lower.Conf.Limit.R2
Upper.Conf.Limit.R2	upper limit of the confidence interval around the population multiple correlation coefficient
Prob.Greater.Upper	proportion of the distribution greater than Lower.Conf.Limit.R2

ci.rc *Confidence Interval for a Regression Coefficient*

Description

A function to calculate a confidence interval for the population regression coefficient of interest using the standard approach and the noncentral approach when the regression coefficients are standardized.

Usage

```
ci.rc(b.k, SE.b.k = NULL, s.Y = NULL, s.X = NULL, N, K, R2.Y_X = NULL,
      R2.k_X.without.k = NULL, conf.level = 0.95, R2.Y_X.without.k = NULL,
      t.value = NULL, alpha.lower = NULL, alpha.upper = NULL,
      Noncentral = FALSE, Suppress.Statement = FALSE, ...)
```

Arguments

b.k	value of the regression coefficient for the k th predictor variable
SE.b.k	standard error for the k th predictor variable
s.Y	standard deviation of Y , the dependent variable
s.X	standard deviation of X , the predictor variable of interest
N	sample size
K	the number of predictors
R2.Y_X	the squared multiple correlation coefficient predicting Y from the k predictor variables
R2.k_X.without.k	the squared multiple correlation coefficient predicting the k th predictor variable (i.e., the predictor of interest) from the remaining $K-1$ predictor variables
conf.level	desired level of confidence for the computed interval (i.e., 1 - the Type I error rate)
R2.Y_X.without.k	the squared multiple correlation coefficient predicting Y from the $K-1$ predictor variable with the k th predictor of interest excluded
t.value	the t-value evaluating the null hypothesis that the population regression coefficient for the k th predictor equals zero
alpha.lower	the Type I error rate for the lower confidence interval limit
alpha.upper	the Type I error rate for the upper confidence interval limit
Noncentral	TRUE/FALSE statement specifying whether or not the noncentral approach to confidence intervals should be used
Suppress.Statement	TRUE/FALSE statement specifying whether or not a statement should be printed that identifies the type of confidence interval formed
...	optional additional specifications for nested functions

Details

This function calls upon `ci.reg.coef` in MBESS, but has a different naming system. See `ci.reg.coef` for more details.

For standardized variables, do not specify the standard deviation of the variables and input the standardized regression coefficient for `b.k`.

Value

Returns the confidence limits for the standardized regression coefficients of interest from the standard approach to confidence interval formation or from the noncentral approach to confidence interval formation using the noncentral t-distribution.

Note

Not all of the values need to be specified, only those that contain all of the necessary information in order to compute the confidence interval (options are thus given for the values that need to be specified).

`ci.reg.coef`

confidence interval for a regression coefficient

Description

A function to calculate a confidence interval around the population regression coefficient of interest using the standard approach and the noncentral approach when the regression coefficients are standardized.

Usage

```
ci.reg.coef(b.j, SE.b.j=NULL, s.Y=NULL, s.X=NULL, N, p, R2.Y_X=NULL,
R2.j_X.without.j=NULL, conf.level=0.95, R2.Y_X.without.j=NULL,
t.value=NULL, alpha.lower=NULL, alpha.upper=NULL, Noncentral=FALSE,
Suppress.Statement=FALSE, ...)
```

Arguments

<code>b.j</code>	value of the regression coefficient for the <i>j</i> th predictor variable
<code>SE.b.j</code>	standard error for the <i>j</i> th predictor variable
<code>s.Y</code>	standard deviation of <i>Y</i> , the dependent variable
<code>s.X</code>	standard deviation of <i>X</i> , the predictor variable of interest
<code>N</code>	sample size
<code>p</code>	the number of predictors
<code>R2.Y_X</code>	the squared multiple correlation coefficient predicting <i>Y</i> from the <i>p</i> predictor variables
<code>R2.j_X.without.j</code>	the squared multiple correlation coefficient predicting the <i>j</i> th predictor variable (i.e., the predictor of interest) from the remaining <i>p</i> -1 predictor variables
<code>conf.level</code>	desired level of confidence for the computed interval (i.e., 1 - the Type I error rate)
<code>R2.Y_X.without.j</code>	the squared multiple correlation coefficient predicting <i>Y</i> from the <i>p</i> -1 predictor variable with the <i>j</i> th predictor of interest excluded
<code>t.value</code>	the <i>t</i> -value evaluating the null hypothesis that the population regression coefficient for the <i>j</i> th predictor equals zero
<code>alpha.lower</code>	the Type I error rate for the lower confidence interval limit
<code>alpha.upper</code>	the Type I error rate for the upper confidence interval limit
<code>Noncentral</code>	TRUE/FALSE statement specifying whether or not the noncentral approach to confidence intervals should be used
<code>Suppress.Statement</code>	TRUE/FALSE statement specifying whether or not a statement should be printed that identifies the type of confidence interval formed
<code>...</code>	optional additional specifications for nested functions

Details

For standardized variables, do not specify the standard deviation of the variables and input the standardized regression coefficient for `b.j`.

Value

Returns the confidence limits specified for the regression coefficient of interest from the standard approach to confidence interval formation or from the noncentral approach to confidence interval formation using the noncentral *t*-distribution.

Note

Not all of the values need to be specified, only those that contain all of the necessary information in order to compute the confidence interval (options are thus given for the values that need to be specified).

The function `ci.rc` in MBESS also calculates the confidence interval for the population (unstandardized) regression coefficient. The function `ci.src` also calculates the confidence interval for the population (standardized) regression coefficient. These two functions perform the same tasks as `ci.reg.coef` does, and are preferred to it because of simpler arguments.

ci.reliability

Confidence Interval for a Reliability Coefficient

Description

A function to calculate the confidence interval for a reliability coefficient using the factor analytic approach or the normal theory approach.

Usage

```
ci.reliability(S = NULL, data = NULL, N = NULL,
model = "True-Score Equivalent", type = "Factor Analytic", conf.level = 0.95,
interval = TRUE, Bootstrap = FALSE, B = 10000, BootstrapCI = "BCa")
```

Arguments

<code>S</code>	symmetric covariance or correlation matrix
<code>data</code>	the data set that the reliability coefficient is obtained from
<code>N</code>	the total sample size
<code>model</code>	the type of measurement model (e.g., "parallel items", "true-score equivalent", or "congeneric model") for a homogeneous single common factor test
<code>type</code>	the type of method to base the formation of the confidence interval on, either the "Factor Analytic" (McDonald, 1999) or "Normal Theory" (van Zyl, Neudecker, & Nel, 2000)
<code>conf.level</code>	the confidence level (i.e., 1-Type I error rate)
<code>interval</code>	whether or not to compute a confidence interval. If <code>FALSE</code> , then only a point estimate of the reliability will be returned.
<code>Bootstrap</code>	whether or not to use the bootstrap to form a confidence interval. The default is to use analytic methods.
<code>B</code>	the number of bootstrap replications
<code>BootstrapCI</code>	the type of bootstrap confidence interval. It can be <code>BCa</code> or <code>percentile</code> .

Details

This function calculates a reliability coefficient for a set of scores based on the measurement model chosen. Thus, coefficient alpha is calculated for parallel items and true-score equivalent; and coefficient omega is calculated for congeneric items. See McDonald (1999) for the assumptions of each of these models. Under the Normal Theory method the asymptotic distribution of the maximum likelihood estimator of coefficient alpha is used for the true-score equivalent model (van Zyl et al., 2000). Note that this model is not optimal for small samples (Yuan & Bentler, 2002), for instance with $N < 20$.

Value

<code>ci.lower</code>	the lower bound of the computed confidence interval
<code>ci.upper</code>	the upper bound of the computed confidence interval
<code>Estimated.reliability</code>	the estimated reliability coefficient
<code>SE.reliability</code>	the standard error of the reliability coefficient
<code>Conf.Level</code>	the confidence level (i.e., 1 - Type I error rate)

ci.reliability.bs *Bootstrap the confidence interval for reliability coefficient*

Description

Obtain the confidence interval for reliability coefficient with bootstrap

Usage

```
ci.reliability.bs(data, model = "Congeneric", type = "Factor Analytic", conf.level
```

Arguments

data	the data set that the reliability coefficient is obtained from
model	the type of measurement model (e.g., "parallel items", "true-score equivalent", or "congeneric model") for a homogeneous single common factor test
type	the type of method to base the formation of the confidence interval on, either the "Factor Analytic" (McDonald, 1999) or "Normal Theory" (van Zyl, Neudecker, & Nel, 2000)
conf.level	the confidence level (i.e., 1-Type I error rate)
B	The number of bootstrap replicates
...	Any other arguments for the boot function

Value

Percentile.Method	Confidence interval obtained with the percentile bootstrap method
BCa.Method	confidence interval obtained with the bias-correct and accelerated bootstrap method

ci.rmsea	<i>Confidence interval for the population root mean square error of approximation</i>
----------	---

Description

Confidence interval for the population root mean square error of approximation (RMSEA).

Usage

```
ci.rmsea(rmsea, df, N, conf.level = 0.95, alpha.lower = NULL,
alpha.upper = NULL)
```

Arguments

rmsea	observed root mean square error of approximation
df	degrees of freedom of the model
N	sample size
conf.level	desired confidence level (e.g., .90, .95, .99)
alpha.lower	the Type I error rate for the lower tail
alpha.upper	the Type I error rate for the upper tail

Details

Provides a confidence interval for the population root mean square error of approximation (RMSEA) using the noncentral chi-square distribution (e.g., Steiger & Lind, 1980).

Value

returns the upper and lower limit as well as the observed value of the RMSEA.

Author(s)

Ken Kelley (University of Notre Dame; <KKelley@ND.Edu>)

References

Steiger, J. H., & Lind, J. C. (1980). *Statistically-based tests for the number of common factors*. Paper presented at the annual Spring meeting of the Psychometric Society, Iowa City, IA.

 ci.sc

Confidence Interval for a Standardized Contrast in a Fixed Effects ANOVA

Description

Function to obtain the confidence interval for a standardized contrast in a fixed effects analysis of variance context.

Usage

```
ci.sc(means = NULL, error.variance = NULL, c.weights = NULL, n = NULL,
      N = NULL, Psi = NULL, ncp = NULL, conf.level = 0.95,
      alpha.lower = NULL, alpha.upper = NULL, df.error = NULL, ...)
```

Arguments

means	a vector of the group means or the means of the particular level of the effect (for fixed effect designs)
error.variance	the common variance of the error (i.e., the mean square error)
c.weights	the contrast weights (the sum of the contrast weights should be zero)
n	sample sizes per group or level of the particular factor (if length 1 it is assumed that the per group/level sample sizes are equal)
N	total sample size
Psi	the (unstandardized) contrast effect, obtained by multiplying the <i>j</i> th mean by the <i>j</i> th contrast weight (this is the unstandardized effect)
ncp	the noncentrality parameter from the t-distribution
conf.level	desired level of confidence for the computed interval (i.e., 1 - the Type I error rate)
alpha.lower	the Type I error rate for the lower confidence interval limit
alpha.upper	the Type I error rate for the upper confidence interval limit

`df.error` the degrees of freedom for the error. In one-way designs, this is simply N -length (means) and need not be specified; it must be specified if the design has multiple factors.

`...` optional additional specifications for nested functions

Value

`Lower.Conf.Limit.Standardized.Contrast`
 the lower confidence limit for the standardized contrast

`Standardized.contrast`
 standardized contrast

`Upper.Conf.Limit.Standardized.Contrast`
 the upper confidence limit for the standardized contrast

Note

Be sure to use the error variance and not its square root (i.e., the standard deviation of the errors).

Examples

```
ci.sc(means=c(2, 4, 9, 13), error.variance=1, c.weights=c(1, -1, -1, 1),
      n=c(3, 3, 3, 3), N=12, conf.level=.95)

ci.sc(means=c(2, 4, 9, 13), error.variance=1, c.weights=c(1, -1, -1, 1),
      n=c(3, 3, 3, 3), N=12, conf.level=.95)

ci.sc(means=c(1.6, 0), error.variance=1, c.weights=c(1, -1), n=c(10, 10),
      N=20, conf.level=.95)
```

<code>ci.sc.ancova</code>	<i>Confidence interval for a standardized contrast in ANCOVA with one covariate</i>
---------------------------	---

Description

Calculate the confidence interval for a standardized contrast in ANCOVA with one covariate. The standardizer (i.e., the divisor) can be either the error standard deviation of the ANOVA model (i.e., the model excluding the covariate) or of the ANCOVA model.

Usage

```
ci.sc.ancova(Psi=NULL, means=NULL, s.anova = NULL, s.ancova,
standardizer = "s.ancova", c.weights, n, x.bar, SSwithin.x,
conf.level = 0.95)
```

Arguments

<code>Psi</code>	unstandardized contrast of adjusted means
<code>means</code>	the vector that contains the adjusted mean of each group
<code>s.anova</code>	the error standard deviation of the ANOVA model
<code>s.ancova</code>	the error standard deviation of the ANCOVA model
<code>standardizer</code>	which error standard deviation the user wants to use, the value of which can be either "s.ancova" or "s.anova"
<code>c.weights</code>	the contrast weights
<code>n</code>	either a single number that indicates the sample size per group, or a vector that contains the sample size of each group
<code>x.bar</code>	a vector that contains the group means of the covariate
<code>SSwithin.x</code>	the sum of squares within groups obtained from the summary table for ANOVA on the covariate
<code>conf.level</code>	the desired confidence interval coverage, (i.e., 1 - Type I error rate)

Value

<code>standardizer</code>	the divisor used in the standardization
<code>psi.limit.lower</code>	the lower confidence limit of the standardized contrast
<code>psi.limit.upper</code>	the upper confidence limit of the standardized contrast

Note

Be sure to use the error variance and not its square root (i.e., the standard deviation of the errors).

If `n` receives a single number, that number is considered as the sample size per group. If `n` is assigned to a vector, the vector is considered as the sample size of each group.

Be sure to use fractions not the integers to specify `c.weights`. For example, in an ANCOVA of four groups, if the user wants to compare the mean of group 1 and 2 with the mean of group 3 and 4, `c.weights` should be specified as `c(0.5, 0.5, -0.5, -0.5)` rather than `c(1, 1, -1, -1)`. Make sure the sum of the contrast weights are zero.

The argument to be assigned to `standardizer` must be either `"s.ancova"` or `"s.anova"`.

n=10, x.bar=c(17, 17.7, 17.4), SSwithin.x=313.37)
```

 ci.sm

Confidence Interval for the Standardized Mean

Description

Function to obtain the exact confidence interval for the standardized mean.

Usage

```
ci.sm(sm = NULL, Mean = NULL, SD = NULL, ncp = NULL, N = NULL,
      conf.level = 0.95, alpha.lower = NULL, alpha.upper = NULL, ...)
```

Arguments

sm	standardized mean
Mean	mean
SD	standard deviation
ncp	noncentral parameter
N	sample size
conf.level	confidence interval coverage (i.e., 1 - Type I error rate); default is .95
alpha.lower	Type I error for the lower confidence limit
alpha.upper	Type I error for the upper confidence limit
...	allows one to potentially include parameter values for inner functions

Details

The user must specify the standardized mean in one and only one of the three ways: a) mean and standard deviation (Mean and SD), b) standardized mean (sm), and c) noncentral parameter (ncp). The confidence level must be specified in one of following two ways: using confidence interval coverage (conf.level), or lower and upper confidence limits (alpha.lower and alpha.upper).

This function uses the exact confidence interval method based on noncentral t distribution. The confidence interval for noncentral t parameter can be obtained from function `conf.limits.nct` in MBESS.

Value

Lower.Conf.Limit.Standardized.Mean	lower confidence limit of the standardized mean
Standardized.Mean	standardized mean
Upper.Conf.Limit.Standardized.Mean	upper confidence limit of the standardized mean

Note

The standardized mean is the mean divided by the standard deviation.

```

ci.smd

Confidence limits for the standardized mean difference.

Description

Function to calculate the confidence limits for the population standardized mean difference using the square root of the pooled variance as the divisor. This function is thus to determine the confidence bounds for the population quantity of what is generally referred to as Cohen's *d* (delta being that population quantity).

Usage

```
ci.smd(ncp=NULL, smd=NULL, n.1=NULL, n.2=NULL, conf.level=.95,
alpha.lower=NULL, alpha.upper=NULL, tol=1e-9, ...)
```

Arguments

<code>n.c.p</code>	is the estimated noncentrality parameter, this is generally the observed <i>t</i> -statistic from comparing the two groups and assumes homogeneity of variance
<code>smd</code>	is the standardized mean difference (using the pooled standard deviation in the denominator)
<code>n.1</code>	is the sample size for Group 1
<code>n.2</code>	is the sample size for Group 2
<code>conf.level</code>	is the confidence level (1-Type I error rate)
<code>alpha.lower</code>	is the Type I error rate for the lower tail
<code>alpha.upper</code>	is the Type I error rate for the upper tail
<code>tol</code>	is the tolerance of the iterative method for determining the critical values
<code>...</code>	allows one to potentially include parameter values for inner functions

Value

<code>Lower.Conf.Limit.smd</code>	The lower bound of the computed confidence interval
<code>smd</code>	The standardized mean difference
<code>Upper.Conf.Limit.smd</code>	The upper bound of the computed confidence interval

Warning

This function uses `conf.limits.nct`, which has as one of its arguments `tol` (and can be modified with `tol` of the present function). If the present function fails to converge (i.e., if it runs but does not report a solution), it is likely that the `tol` value is too restrictive and should be increased by a factor of 10, but probably by no more than 100. Running the function `conf.limits.nct` directly will report the actual probability values of the limits found. This should be done if any modification to `tol` is necessary in order to ensure acceptable confidence limits for the noncentral-*t* parameter have been achieved.

Examples

```
# Examples Steiger and Fouladi example values.
ci.smd(ncp=2.6, n.1=10, n.2=10, conf.level=1-.05)
ci.smd(ncp=2.4, n.1=300, n.2=300, conf.level=1-.05)
```

ci.smd.c

Confidence limits for the standardized mean difference using the control group standard deviation as the divisor.

Description

Function to calculate the confidence limits for the standardized mean difference using the control group standard deviation as the divisor (Glass's g).

Usage

```
ci.smd.c(ncp = NULL, smd.c = NULL, n.C = NULL, n.E = NULL,
conf.level = 0.95, alpha.lower = NULL, alpha.upper = NULL,
tol = 1e-09, ...)
```

Arguments

ncp	is the estimated noncentrality parameter, this is generally the observed t -statistic from comparing the control and experimental group (assuming homogeneity of variance)
smd.c	is the standardized mean difference (using the control group standard deviation in the denominator)
n.C	is the sample size for the control group
n.E	is the sample size for experimental group
conf.level	is the confidence level (1-Type I error rate)
alpha.lower	is the Type I error rate for the lower tail
alpha.upper	is the Type I error rate for the upper tail
tol	is the tolerance of the iterative method for determining the critical values
...	Potentially include parameter for inner functions

Value

<code>Lower.Conf.Limit.smd.c</code>	The lower bound of the computed confidence interval
<code>smd.c</code>	The standardized mean difference based on the control group standard deviation
<code>Upper.Conf.Limit.smd.c</code>	The upper bound of the computed confidence interval

Warning

This function uses `conf.limits.nct`, which has as one of its arguments `tol` (and can be modified with `tol` of the present function). If the present function fails to converge (i.e., if it runs but does not report a solution), it is likely that the `tol` value is too restrictive and should be increased by a factor of 10, but probably by no more than 100. Running the function `conf.limits.nct` directly will report the actual probability values of the limits found. This should be done if any modification to `tol` is necessary in order to ensure acceptable confidence limits for the noncentral- t parameter have been achieved.

ci.snr

Confidence Interval for the Signal-To-Noise Ratio

Description

Function to obtain the exact confidence interval for the signal-to-noise ratio (i.e., the variance of the specific factor over the error variance).

Usage

```
ci.snr(F.value = NULL, df.1 = NULL, df.2 = NULL, N = NULL, conf.level = 0.95,
       alpha.lower = NULL, alpha.upper = NULL, ...)
```

Arguments

<code>F.value</code>	observed F-value from the analysis of variance
<code>df.1</code>	numerator degrees of freedom
<code>df.2</code>	denominator degrees of freedom
<code>N</code>	sample size
<code>conf.level</code>	confidence interval coverage (i.e., 1 - Type I error rate), default is .95
<code>alpha.lower</code>	Type I error for the lower confidence limit
<code>alpha.upper</code>	Type I error for the upper confidence limit
<code>...</code>	allows one to potentially include parameter values for inner functions

Details

The confidence level must be specified in one of following two ways: using confidence interval coverage (`conf.level`), or lower and upper confidence limits (`alpha.lower` and `alpha.upper`).

This function uses the confidence interval transformation principle (Steiger, 2004) to transform the confidence limits for the noncentrality parameter to the confidence limits for the population's signal-to-noise ratio. The confidence interval for noncentral F parameter can be obtained from function `conf.limits.ncf` in MBESS, which is used within this function.

Value

Returns the confidence limits for the signal-to-noise ratio.

`Lower.Limit.Signal.to.Noise.Ratio`
lower limit for signal to noise ratio

`Upper.Limit.Signal.to.Noise.Ratio`
upper limit for signal to noise ratio

Note

The signal to noise ratio is defined as the variance due to the particular factor over the error variance (i.e., the mean square error).

ci.src

Confidence Interval for a Standardized Regression Coefficient

Description

Function to obtain the confidence interval for a standardized regression coefficient.

Usage

```
ci.src(beta.k = NULL, SE.beta.k = NULL, N = NULL, K = NULL, R2.Y_X = NULL,
R2.k_X.without.k = NULL, conf.level = 0.95, R2.Y_X.without.k = NULL,
t.value = NULL, b.k = NULL, SE.b.k = NULL, s.Y = NULL, s.X = NULL,
alpha.lower = NULL, alpha.upper = NULL, Suppress.Statement = FALSE, ...)
```

Arguments

<code>beta.k</code>	the standardized regression coefficient
<code>SE.beta.k</code>	the standard error of the standardized regression coefficient
<code>N</code>	sample size
<code>K</code>	the number of predictors
<code>R2.Y_X</code>	the squared multiple correlation coefficient predicting Y from the k predictor variables
<code>R2.k_X.without.k</code>	the squared multiple correlation coefficient predicting the k th predictor variable (i.e., the predictor of interest) from the remaining $p-1$ predictor variables
<code>conf.level</code>	desired level of confidence for the computed interval (i.e., $1 -$ the Type I error rate)
<code>R2.Y_X.without.k</code>	the squared multiple correlation coefficient predicting Y from the $p-1$ predictor variable with the k th predictor of interest excluded
<code>t.value</code>	the t-value evaluating the null hypothesis that the population regression coefficient for the k th predictor equals zero
<code>b.k</code>	the unstandardized regression coefficient
<code>SE.b.k</code>	the standard error of the unstandardized regression coefficient
<code>s.Y</code>	standard deviation of Y , the dependent variable
<code>s.X</code>	standard deviation of X , the predictor variable of interest
<code>alpha.lower</code>	the Type I error rate for the lower confidence interval limit
<code>alpha.upper</code>	the Type I error rate for the upper confidence interval limit
<code>Suppress.Statement</code>	TRUE/FALSE statement specifying whether or not a statement should be printed that identifies the type of confidence interval formed
<code>...</code>	optional additional specifications for nested functions

Details

For standardized variables, do not specify the standard deviation of the variables and input the standardized regression coefficient for `b.k`.

Value

Returns the confidence limits specified for the regression coefficient of interest from the standard approach to confidence interval formation or from the noncentral approach to confidence interval formation using the noncentral t-distribution.

Note

This function calls upon `ci.reg.coef` in MBESS, but has a different naming scheme. See `ci.reg.coef` for more details.

To form a confidence interval for the unstandardized regression coefficient, use `ci.rc`. This function is used to form a confidence interval for the standardized regression coefficient.

Not all of the values need to be specified, only those that contain all of the necessary information in order to compute the confidence interval (options are thus given for the values that need to be specified).

`ci.srsnr`

Confidence Interval for the Square Root of the Signal-To-Noise Ratio

Description

Function to calculate the exact confidence interval for the square root of the signal-to-noise ratio.

Usage

```
ci.srsnr(F.value = NULL, df.1 = NULL, df.2 = NULL, N = NULL,
conf.level = 0.95, alpha.lower = NULL, alpha.upper = NULL, ...)
```

Arguments

<code>F.value</code>	observed F -value from the analysis of variance
<code>df.1</code>	numerator degrees of freedom
<code>df.2</code>	denominator degrees of freedom
<code>N</code>	sample size
<code>conf.level</code>	confidence interval coverage (i.e., 1 - Type I error rate); default is .95
<code>alpha.lower</code>	Type I error for the lower confidence limit
<code>alpha.upper</code>	Type I error for the upper confidence limit
<code>...</code>	allows one to potentially include parameter values for inner functions

Details

The confidence level must be specified in one of following two ways: using confidence interval coverage (`conf.level`), or lower and upper confidence limits (`alpha.lower` and `alpha.upper`).

The square root of the signal-to-noise ratio is defined as the standard deviation due to the particular factor over the standard deviation of the error (i.e., the square root of the mean square error). This function uses the confidence interval transformation principle (Steiger, 2004) to transform the confidence limits for the noncentrality parameter to the confidence limits for square root of signal-to-noise ratio. The confidence interval for noncentral F parameter can be obtained from function `conf.limits.ncf` in MBESS.

Value

Returns the square root of the confidence limits for the signal to noise ratio.

`Lower.Limit.of.the.Square.Root.of.the.Signal.to.Noise.Ratio`
lower limit of the square root of the signal to noise ratio

`Upper.Limit.of.the.Square.Root.of.the.Signal.to.Noise.Ratio`
upper limit of the square root of the signal to noise ratio

conf.limits.nc.chisq
```

Confidence limits for noncentral chi square parameters

Description

Function to determine the noncentral parameter that leads to the observed Chi . Square-value, so that a confidence interval for the population F-value can be conducted. Used for forming confidence intervals around noncentral parameters (given the monotonic relationship between the F-value and the noncentral value).

Usage

```
conf.limits.nc.chisq(Chi.Square=NULL, conf.level=.95, df=NULL,
alpha.lower=NULL, alpha.upper=NULL, tol=1e-9, Jumping.Prop=.10)
```

Arguments

Chi.Square	the observed chi-square value
conf.level	the desired degree of confidence for the interval
df	the degrees of freedom
alpha.lower	Type I error for the lower confidence limit
alpha.upper	Type I error for the upper confidence limit
tol	tolerance for iterative convergence
Jumping.Prop	Value used in the iterative scheme to determine the noncentral parameters necessary for confidence interval construction using noncentral chi square-distributions (0 < Jumping.Prop < 1)

Details

If the function fails (or if a function relying upon this function fails), adjust the `Jumping.Prop` (to a smaller value).

Value

Lower.Limit Value of the distribution with Lower.Limit noncentral value that has at its specified quantile Chi.Square

Prob.Less.Lower Proportion of cases falling below Lower.Limit

Upper.Limit Value of the distribution with Upper.Limit noncentral value that has at its specified quantile Chi.Square

Prob.Greater.Upper Proportion of cases falling above Upper.Limit

conf.level=NULL, df=15)
```

conf.limits.ncf *Confidence limits for noncentral F parameters*

Description

Function to determine the noncentral parameter that leads to the observed F-value, so that a confidence interval around the population F-value can be conducted. Used for forming confidence intervals around noncentral parameters (given the monotonic relationship between the F-value and the noncentral value).

Usage

```
conf.limits.ncf(F.value = NULL, conf.level = .95, df.1 = NULL,
df.2 = NULL, alpha.lower = NULL, alpha.upper = NULL, tol = 1e-09,
Jumping.Prop = 0.1)
```

Arguments

<code>F.value</code>	the observed F-value
<code>conf.level</code>	the desired degree of confidence for the interval
<code>df.1</code>	the numerator degrees of freedom
<code>df.2</code>	the denominator degrees of freedom
<code>alpha.lower</code>	Type I error for the lower confidence limit
<code>alpha.upper</code>	Type I error for the upper confidence limit
<code>tol</code>	tolerance for iterative convergence
<code>Jumping.Prop</code>	Value used in the iterative scheme to determine the noncentral parameters necessary for confidence interval construction using noncentral F-distributions ($0 < \text{Jumping.Prop} < 1$)

Details

This function is the relied upon by the `ci.R2` and `ss.aipe.R2`. If the function fails (or if a function relying upon this function fails), adjust the `Jumping.Prop` (to a smaller value).

Value

<code>Lower.Limit</code>	Value of the distribution with <code>Lower.Limit</code> noncentral value that has at its specified quantile <code>F.value</code>
<code>Prob.Less.Lower</code>	Proportion of cases falling below <code>Lower.Limit</code>
<code>Upper.Limit</code>	Value of the distribution with <code>Upper.Limit</code> noncentral value that has at its specified quantile <code>F.value</code>
<code>Prob.Greater.Upper</code>	Proportion of cases falling above <code>Upper.Limit</code>

df.2 = 100)

# A one sided confidence interval.
conf.limits.ncf(F.value = 5, conf.level = NULL, df.1 = 5,
df.2 = 100, alpha.lower = .05, alpha.upper = 0, tol = 1e-09,
Jumping.Prop = 0.1)
```

conf.limits.nct *Confidence limits for a noncentrality parameter from a t-distribution*

Description

Function to determine the noncentrality parameters necessary to form a confidence interval around the population noncentrality parameter and related parameters. Due to the difficulties in estimating the necessary values, three different methods are implemented within the present function (`conf.limits.nct.M1`, `conf.limits.nct.M2`, and `conf.limits.nct.M3`) and the best set of results are taken.

Usage

```
conf.limits.nct(ncp, df, conf.level = 0.95, alpha.lower = NULL,
alpha.upper = NULL, t.value, tol = 1e-09, sup.int.warns = TRUE,
method = "all", ...)
```

Arguments

<code>ncp</code>	the noncentrality parameter (e.g., observed t-value) of interest.
<code>df</code>	the degrees of freedom.
<code>conf.level</code>	the level of confidence for a symmetric confidence interval.
<code>alpha.lower</code>	the proportion of values beyond the lower limit of the confidence interval (cannot be used with <code>conf.level</code>).
<code>alpha.upper</code>	the proportion of values beyond the upper limit of the confidence interval (cannot be used with <code>conf.level</code>).
<code>t.value</code>	alias for <code>ncp</code>
<code>tol</code>	is the tolerance of the iterative method for determining the critical values.
<code>sup.int.warns</code>	Suppress internal warnings (from internal functions): TRUE or FALSE
<code>method</code>	which of the three methods should be used: "all", "1", "2", "3" ("all" is default).
<code>...</code>	allows one to potentially include parameter values for inner functions

Details

Function for finding the upper and lower confidence limits for a noncentral parameter from a non-central *t*-distribution with `df` degrees of freedom. This function is especially helpful when forming confidence intervals around standardized mean differences (i.e., Cohen's *d*; Glass's *g*; Hedges *g'*), standardized regression coefficients, and coefficients of variations. The `Lower.Limit` and the `Upper.Limit` values correspond to the noncentral parameters of a *t*-distribution with `df` degrees of freedom whose upper and lower tails contain the desired proportion of the curves, respectively. When `ncp` is zero, the `Lower.Limit` and `Upper.Limit` are simply the desired quantiles of the central *t*-distribution with `df` degrees of freedom.

See the documentation and code for each of the three methods (if interested). Each of the three methods should reach the same values for the confidence limits. However, due to the iterative nature of the functions, one function may arrive at a more optimal solution. Furthermore, in some situations one (or more) functions could fail to find the optimum values, which necessitates the use of multiple methods to (essentially) ensure that optimal values are found.

Value

`Lower.Limit` Value of the distribution with `Lower.Limit` noncentral value that has at its specified quantile `F.value`

`Prob.Less.Lower` Proportion of the distribution beyond (i.e., less than) `Lower.Limit`

`Upper.Limit` Value of the distribution with `Upper.Limit` noncentral value that has at its specified quantile `F.value`

`Prob.Greater.Upper` Proportion of the distribution beyond (i.e., larger than) `Upper.Limit`

Warning

At the present time, the largest `ncp` that R can accurately handle is 37.62.

```

```
conf.limits.nct.M1 Confidence limits for a noncentrality parameter from a t-distribution
(Method 1 of 3)
```

Description

Largely internal function to determine the noncentrality parameters necessary to form a confidence interval for the population noncentrality parameter and related parameters. Method 1 uses the `optimize` function to determine the critical values. This function requires the `ncp` to be positive, but the function that should be used `conf.limits.nct` does not.

Usage

```
conf.limits.nct.M1(ncp, df, conf.level = .95, alpha.lower = NULL,
alpha.upper = NULL, min.ncp = -3 * ncp, max.ncp = 3 * ncp,
tol = 1e-09, sup.int.warns = TRUE, ...)
```

Arguments

<code>ncp</code>	the noncentrality parameter (e.g., observed t-value) of interest
<code>df</code>	the degrees of freedom
<code>conf.level</code>	the level of confidence for a symmetric confidence interval
<code>alpha.lower</code>	the proportion of values beyond the lower limit of the confidence interval (cannot be used with <code>conf.level</code>)
<code>alpha.upper</code>	the proportion of values beyond the upper limit of the confidence interval (cannot be used with <code>conf.level</code>)
<code>min.ncp</code>	lower noncentral parameter from which to start the search process
<code>max.ncp</code>	lower noncentral parameter from which to start the search process
<code>tol</code>	is the tolerance of the iterative method for determining the critical values
<code>sup.int.warns</code>	Suppress internal warnings (from internal functions): TRUE or FALSE
<code>...</code>	allows one to potentially include parameter values for inner functions

Value

<code>Lower.Limit</code>	Value of the distribution with <code>Lower.Limit</code> noncentral value that has at its specified quantile <code>F.value</code>
<code>Prob.Less.Lower</code>	Proportion of the distribution beyond (i.e., less than) <code>Lower.Limit</code>

Upper.Limit Value of the distribution with Upper.Limit noncentral value that has at its specified quantile F.value
 Prob.Greater.Upper Proportion of the distribution beyond (i.e., larger than) Upper.Limit

conf.limits.nct.M2 *Confidence limits for a noncentrality parameter from a t-distribution (Method 2 of 3)*

Description

Largely internal function to determine the noncentrality parameters necessary to form a confidence interval around the population noncentrality parameter and related parameters. Method 2 uses the nlm function to determine the critical values. This function requires the ncp to be positive, but the function that should be used conf.limits.nct does not.

Usage

```
conf.limits.nct.M2(ncp = ncp, df = df, conf.level = .95, alpha.lower = NULL,
alpha.upper = NULL, tol = 1e-09, sup.int.warns = TRUE, ...)
```

Arguments

ncp	the noncentrality parameter (e.g., observed t-value) of interest
df	the degrees of freedom
conf.level	the level of confidence for a symmetric confidence interval
alpha.lower	the proportion of values beyond the lower limit of the confidence interval (cannot be used with conf.level)
alpha.upper	the proportion of values beyond the upper limit of the confidence interval (cannot be used with conf.level)
tol	is the tolerance of the iterative method for determining the critical values
sup.int.warns	Suppress internal warnings (from internal functions): TRUE or FALSE
...	allows one to potentially include parameter values for inner functions

Value

Lower.Limit Value of the distribution with Lower.Limit noncentral value that has at its specified quantile F.value

Prob.Less.Lower
Proportion of the distribution beyond (i.e., less than) Lower.Limit

Upper.Limit Value of the distribution with Upper.Limit noncentral value that has at its specified quantile F.value

Prob.Greater.Upper
Proportion of the distribution beyond (i.e., larger than) Upper.Limit

conf.limits.nct.M3 *Confidence limits for a noncentrality parameter from a t-distribution (Method 3 of 3)*

Description

Largely internal function to determine the noncentrality parameters necessary to form a confidence interval around the population noncentrality parameter and related parameters. Method 3 uses an iterative scheme in order to determine the critical values. This function requires the ncp to be positive, but the function that should be used conf.limits.nct does not.

Usage

```
conf.limits.nct.M3(ncp, df, conf.level = .95, alpha.lower = NULL,
alpha.upper = NULL, tol = 1e-09, sup.int.warns = TRUE,
max.steps = 2500, ...)
```

Arguments

ncp the noncentrality parameter (e.g., observed t-value) of interest

df the degrees of freedom

conf.level the level of confidence for a symmetric confidence interval

alpha.lower the proportion of values beyond the lower limit of the confidence interval (cannot be used with conf.level)

alpha.upper the proportion of values beyond the upper limit of the confidence interval (cannot be used with conf.level)

tol is the tolerance of the iterative method for determining the critical values

```

sup.int.warns      Suppress internal warnings (from internal functions): TRUE or FALSE
max.steps          maximum number of iterations when finding the lower and upper confidence
                  limit
...               allows one to potentially include parameter values for inner functions

```

Value

```

Lower.Limit        Value of the distribution with Lower.Limit noncentral value that has at its
                  specified quantile F.value
Prob.Less.Lower    Proportion of the distribution beyond (i.e., less than) Lower.Limit
Upper.Limit        Value of the distribution with Upper.Limit noncentral value that has at its
                  specified quantile F.value
Prob.Greater.Upper Proportion of the distribution beyond (i.e., larger than) Upper.Limit

```

Cor.Mat.Lomax *Correlation matrix for Lomax (1983) data set*

Description

Correlation matrix for Lomax (1983) data set

Usage

```
data(Cor.Mat.Lomax)
```

Details

Variables 1 through 14 in the correlation matrix are, respectively:

Variables

- (1) DRS-consonant sounds
- (2) DRS-consonant blends and diagraphs
- (3) DRS-common syllables or phonograms
- (4) DRS-blending
- (5) WRAT-total raw score
- (6) DRS-total correct both lists
- (7) DRS-total words read correct oral
- (8) DRS-wpm first oral passage
- (9) DRS-wpm first silent passage
- (10) DRS-mean wpm oral passages read
- (11) DRS-mean wpm silent passages read
- (12) DRS-total correct oral comprehension
- (13) DRS-total correct silent comprehension
- (14) CTBS-comprehension ESS scores

DRS refers to Diagnostic Reading Scales, WRAT refers to Wide Range Achievement Test, and CTBS refers to Comprehensive Tests of basic skills.

The model was designed to study the causal relationship between the phonological, word recognition, reading rate, and comprehension components of the reading process. There are four latent variables in the model: (a) phonological; (b) word recognition; (c) reading rate; (d) reading comprehension.

Phonological is indicated by (a) DRS-consonant sounds; (b) DRS-consonant blends and diagraphs; (c) DRS-common syllables or phonograms; (d) DRS-blending.

Word recognition is indicated by (a) WRAT-total raw score; (b) DRS-total correct both lists; (c) DRS-total words read correct oral

Reading rate is indicated by (a) DRS-wpm first oral passage; (b) DRS-wpm first silent passage; (c) DRS-mean wpm oral passages read; (d) DRS-mean wpm silent passages read.

Reading comprehension is indicated by (a) DRS-total correct oral comprehension; (b) DRS-total correct silent comprehension; (c) CTBS-comprehension ESS scores.

Cor.Mat.MM

*Correlation matrix for Maruyama & McGarvey (1980) data set***Description**

Correlation matrix for Maruyama & McGarvey (1980) data set

Usage

data(Cor.Mat.MM)

Details

Variables 1 through 13 in the correlation matrix are, respectively:

- Variables
- (1) seating popularity
 - (2) playground popularity
 - (3) schoolwork popularity
 - (4) verbal achievement
 - (5) verbal grades
 - (6) Duncan SEI
 - (7) education of head of house
 - (8) No. of rooms over No. of persons
 - (9) Raven Progressive Matrices
 - (10) Peabody PVT
 - (11) father's evaluation
 - (12) mothers evaluation
 - (13) teacher's evaluation

The model was designed to examine whether acceptance by significant others (i.e., parents, teachers, and peers) causes improved scholastic achievement. There are five latent variables in the model: (a) SES, socio-economic status; (b) ABL, academic ability; (c) ACH, achievement; (d) ASA, acceptance by significant adults; (e) APR, acceptance by peers.

SES is indicated by (a) SEI, Duncan Socioeconomic Index of Occupations; (b) EDHH, educational attainment of the head of the household; (c) R/P, ratio of rooms in the house to persons living in the house.

ACH is indicated by (a) VACH, standardized verbal test scores; (b) VGR, verbal grades.

ABL is indicated by (a) PEA, Peabody Picture Vocabulary Test; (b) RAV, Raven Progressive Matrices.

ASA is indicated by (a) FEV, father's evaluation; (b) MEV, mother's evaluation; (c) TEV, teacher's evaluation.

APR is indicated by (a) PPOP, playground popularity; (b) SPOP, seating popularity; (c) WPOP, schoolwork popularity.

`cor2cov`*Correlation Matrix to Covariance Matrix Conversion*

Description

Function to convert a correlation matrix to a covariance matrix.

Usage

```
cor2cov(cor.mat, sd, discrepancy=1e-5)
```

Arguments

<code>cor.mat</code>	the correlation matrix to be converted
<code>sd</code>	a vector that contains the standard deviations of the variables in the correlation matrix
<code>discrepancy</code>	a neiboughood of 1, such that numbers on the main diagonal of the correlation matrix will be considered as equal to 1 if they fall in this neiboughood

Details

The correlation matrix to convert can be either symmetric or triangular. The covariance matrix returned is always a symmetric matrix.

Note

The correlation matrix input should be a square matrix, and the length of `sd` should be equal to the number of variables in the correlation matrix (i.e., the number of rows/columns). Sometimes the correlation matrix input may not have exactly 1's on the main diagonal, due to, eg, rounding; `discrepancy` specifies the allowable discrepancy so that the function still considers the input as a correlation matrix and can proceed (but the function does not change the numbers on the main diagonal).

Author(s)

Ken Kelley (University of Notre Dame; <KKelley@ND.Edu>), Keke Lai

covmat.from.cfm *Covariance matrix from confirmatory (single) factor model.*

Description

Function calculates a covariance matrix using the specified Lambda and Psi.Square values from a confirmatory factor model approach (McDonald, 1999).

Usage

```
covmat.from.cfm(Lambda, Psi.Square, tol.det = 1e-05)
```

Arguments

Lambda	the vector of population factor loadings
Psi.Square	the vector of population error variances
tol.det	the specified tolerance for the determinant

Value

Population.Covariance	the population covariance matrix
True.Covariance	the true covariance matrix
True.Covariance	the error covariance matrix

Author(s)

Ken Kelley (University of Notre Dame; <KKelley@ND.Edu>); Leann Terry (Indiana University; <ljterry@Indiana.Edu>)

References

```

cv

Function to calculate the regular (and biased) estimate of the coefficient of variation or the unbiased estimate of the coefficient of variation.

Description

Returns the estimated coefficient of variation or the unbiased estimate of the coefficient of variation.

Usage

```
cv(C.of.V=NULL, mean=NULL, sd=NULL, N=NULL, unbiased=FALSE)
```

Arguments

C.of.V	Usual estimate of the coefficient of variation (C.of.V=sd/mean)
mean	observed mean
sd	observed standard deviation (based on N-1 in the denominator of the variance)
N	sample size
unbiased	return the unbiased estimate of the coefficient of variation

Details

A function to calculate the usual estimate of the coefficient of variation or its unbiased estimate.

Value

Returns the unbiased estimate for the standard deviation.

Author(s)

Ken Kelley (University of Notre Dame; <KKelley@ND.Edu>)

Examples

```
cv(mean=100, sd=15)
cv(mean=100, sd=15, N=50, unbiased=TRUE)
cv(C.of.V=.15, N=2, unbiased=TRUE)
```

`Expected.R2`*Expected value of the squared multiple correlation coefficient*

Description

Returns the expected value of the squared multiple correlation coefficient given the population squared multiple correlation coefficient, sample size, and the number of predictors

Usage

```
Expected.R2(Population.R2, N, p)
```

Arguments

<code>Population.R2</code>	population squared multiple correlation coefficient
<code>N</code>	sample size
<code>p</code>	the number of predictor variables

Details

Uses the hypergeometric function as discussed in and section 28 of Stuart, Ord, and Arnold (1999) in order to obtain the *correct* value for the squared multiple correlation coefficient. Many times an exact value is given that ignores the hypergeometric function. This function yields the correct value.

Value

Returns the expected value of the squared multiple correlation coefficient.

Note

Uses package `gsl` and its `hyperg_2F1` function.

Author(s)

Ken Kelley (University of Notre Dame; <KKelley@ND.Edu>)

# Expected.R2(.5, 10000, 5)
```

```
F.and.R2.Noncentral.Conversion
```

Conversion functions from noncentral noncentral values to their corresponding and vice versa, for those related to the F-test and R Square.

Description

Given values of test statistics (and the appropriate additional information) the value of the non-central values can be obtained. Likewise, given noncentral values (and the appropriate additional information) the value of the test statistic can be obtained.

Usage

```
Rsquare2F(R2 = NULL, df.1 = NULL, df.2 = NULL, p = NULL, N = NULL)
```

```
F2Rsquare(F.value = NULL, df.1 = NULL, df.2 = NULL)
```

```
Lambda2Rsquare(Lambda = NULL, N = NULL)
```

```
Rsquare2Lambda(R2 = NULL, N = NULL)
```

Arguments

R2	squared multiple correlation coefficient (population or observed)
df.1	degrees of freedom for the numerator of the F-distribution
df.2	degrees of freedom for the denominator of the F-distribution
p	number of predictor variables for R2
N	sample size
F.value	The obtained F value from a test of significance for the squared multiple correlation coefficient
Lambda	The noncentral parameter from an F-distribution

Details

These functions are especially helpful for the search for confidence intervals for noncentral parameters, as they convert to and from related quantities.

Value

Returns the converted value from the specified function.

Gardner.LD

The Gardner learning data, which was used by L.R. Tucker

Description

Repeated measures data on 24 participants, each with 21 trials (each trial based on 20 replications).

Usage

```
data(Gardner.LD)
```

Format

A data frame where the rows represent the timepoints for the individuals.

ID : a numeric vector

Trial : a numeric vector

Score : a numeric vector

Group : a numeric vector

Details

The 24 participants of this study were presented with 420 presentations of four letters where the task was to identify the next letter that was to be presented. Twelve of the participants (Group 1) were presented the letters S, L, N, and D with probabilities .70, .10, .10, and .10, respectively. The other 12 participants (Group 2) were presented the letter L with probability .70 and three other letters, each with a probability of .10. The 420 presentations were (arbitrarily it seems) grouped into 21 trials of 20 presentations. The score for each trial was the number of times the individual correctly guessed the dominant letter. The participants were naive to the probability that the letters would be presented. Other groups of individuals (although the data is not available) were tested under a different probability structure. The data given here is thus known as the 70-10-10-10 group from Gardner's paper. L. R. Tucker used this data set to illustrate methods for understanding change.

 HS.data

Complete Data Set of Holzinger and Swineford's (1939) Study

Description

The *complete* data set of scores of 301 subjects in 26 tests in Holzinger and Swineford's (1939) study.

Usage

```
data(HS.data)
```

Format

A data frame with 301 observations on the following 32 variables.

```
id subject's ID number
Gender subject's gender
grade the grade the subject is on
agey the year part of the subject's age
agem the month part of the subject's age
school the school the subject is from
visual scores on visual perception test, test 1
cubes scores on cubes test, test 2
paper scores on paper form board test, test 3
flags scores on lozenges test, test 4
general scores on general information test, test 5
paragrap scores on paragraph comprehension test, test 6
sentence scores on sentence completion test, test 7
wordc scores on word classification test, test 8
wordm scores on word meaning test, test 9
addition scores on add test, test 10
code scores on code test, test 11
```

counting scores on counting groups of dots test, test 12
 straight scores on straight and curved capitals test, test 13
 wordr scores on word recognition test, test 14
 numberr scores on number recognition test, test 15
 figurer scores on figure recognition test, test 16
 object scores on object-number test, test 17
 numberf scores on number-figure test, test 18
 figurew scores on figure-word test, test 19
 deduct scores on deduction test, test 20
 numeric scores on numerical puzzles test, test 21
 problemr scores on problem reasoning test, test 22
 series scores on series completion test, test 23
 arithmet scores on Woody-McCall mixed fundamentals, form I test, test 24
 paperrev scores on additional paper form board test, test 25
 flagssub scores on flags test, test 26

Details

Holzinger and Swineford (1939) data is widely cited, but generally only the Grant-White School data is used. The present dataset contains the complete data of Holzinger and Swineford (1939).

A total number of 301 pupils from Paster School and Grant-White School participated in Holzinger and Swineford's (1939) study. This study consists of 26 tests, which are used to measure the subjects' spatial, verbal, mental speed, memory, and mathematical ability.

The spatial tests consist of `visual`, `cubes`, `paper`, `flags`, `paperrev`, and `flagssub`. The test 25, paper form board test (`paperrev`), can be used as a substitute for test 3, paper form board test (`paper`). The test 26, flags test (`flagssub`), is a possible substitute for test 4, lozenges test (`flags`).

The verbal tests consist of `general`, `paragrap`, `sentence`, `wordc`, and `wordm`.

The speed tests consist of `addition`, `code`, `counting`, and `straight`.

The memory tests consist of `wordr`, `numberr`, `figurer`, `object`, `numberf`, and `figurew`.

The mathematical-ability tests consist of `deduct`, `numeric`, `problemr`, `series`, and `arithmet`.

intr.plot

*Regression Surface Containing Interaction***Description**

To plot a three dimensional figure of a multiple regression surface containing one two-way interaction.

Usage

```
intr.plot(b.0, b.x, b.z, b.xz, x.min = NULL, x.max = NULL, z.min = NULL,
z.max = NULL, n.x = 50, n.z = 50, x = NULL, z = NULL, col = "lightblue",
hor.angle = -60, vert.angle = 15, xlab = "Value of X", zlab = "Value of Z",
ylab = "Dependent Variable", expand = 0.5, lines.plot=TRUE, col.line = "red",
line.wd = 2, gray.scale = FALSE, ticktype="detailed", ...)
```

Arguments

b.0	the intercept
b.x	regression coefficient for predictor x
b.z	regression coefficient for predictor z
b.xz	regression coefficient for the interaction of predictors x and z
x.min, x.max, z.min, z.max	ranges of x and z. The regression surface defined by these limits will be plotted.
n.x	number of elements in predictor vector x; number of points to be plotted on the regression surface; default is 50
n.z	number of elements in predictor vector z; number of points to be plotted on the regression surface; default is 50
x	a specific predictor vector x, used instead of x.max and x.min
z	a specific predictor vector z, used instead of z.max and z.min
col	color of the regression surface; default is "lightbule"
hor.angle	rotate the regression surface horizontally; default is -60 degree
vert.angle	rotate the regression surface vertically; default is 15 degree
xlab	title for the axis which the predictor x is on
zlab	title for the axis which the predictor z is on
ylab	title for the axis which the dependent y is on
expand	default is 0.5; expansion factor applied to the axis of the dependent variable. Often used with $0 < \text{expand} < 1$ to shrink the plotting box in the direction of the dependent variable's axis.
lines.plot	whether or not to plot on the regression surface regression lines holding z at values 0, 1, -1, 2, -2 above the mean; default is TRUE.
col.line	the color of regression lines plotted on the regression surface; default is red

line.wd	the width of regression lines plotted on the regression surface; default is 2
gray.scale	whether or not to plot the figure black and white; default is FALSE
ticktype	whether the axes should be plotted with ("detailed") or without ("simple") tick marks
...	allows one to potentially include parameter values for inner functions

Details

The user can input either the limits of x and z, or specific x and z vectors, to draw the regression surface. If the user inputs simply the limits of the predictors, the function would generate predictor vectors for plotting. If the user inputs specific predictor vectors, the function would plot the regression surface based on those vectors.

Note

If the user enters specific vectors instead of the ranges of predictors, please make sure elements in those vectors are in ascending order. This is required by function `persp`, which is used within this function.

ticktype="detailed", nticks=8)
```

intr.plot.2d	<i>Plotting Conditional Regression Lines with Interactions in Two Dimensions</i>
--------------	--

Description

To plot regression lines for one two-way interactions, holding one of the predictors (in this function, z) at values -2, -1, 0, 1, and 2 standard deviations above the mean.

Usage

```
intr.plot.2d(b.0, b.x, b.z, b.xz, x.min=NULL, x.max=NULL, x=NULL,
n.x=50, mean.z=NULL, sd.z=NULL, z=NULL, xlab="Value of X",
ylab="Dependent Variable", sd.plot=TRUE, sd2.plot=TRUE, sd_1.plot=TRUE,
sd_2.plot=TRUE, type.sd=2, type.sd2=3, type.sd_1=4, type.sd_2=5,
legend.pos="bottomright", legend.on=TRUE, ... )
```

Arguments

b.0	the intercept
b.x	regression coefficient for predictor x
b.z	regression coefficient for predictor z
b.xz	regression coefficient for the interaction of predictors x and z
x.min, x.max	the range of x used in the plot
x	a specific predictor vector x, used instead of x.min and x.max
n.x	number of elements in predictor vector x
mean.z	mean of predictor z
sd.z	standard deviation of predictor z
z	a specific predictor vector z, used instead of z.min and z.max
xlab	title for the axis which the predictor x is on
ylab	title for the axis which the dependent y is on
sd.plot, sd2.plot, sd_1.plot, sd_2.plot	whether or not to plot the regression line holding z at values 1, 2, -1, and -2 standard deviations above the mean, respectively. Default values are all TRUE.

type.sd, type.sd2, type.sd_1, type.sd_2
 types of lines to be plotted holding z at values 1, 2, -1, and -2 standard deviations above the mean, respectively. Default are line type 2,3,4, and 5, respectively.

legend.pos position of the legend; possible options are "bottomright", "bottom", "bottomleft", "left", "center", "right", "topleft", "top", and "topright".

legend.on whether or not to show the legend

... allows one to potentially include parameter values for inner functions

Details

To input the predictor x, one can use either the limits of x (x.max and x.min), or a specific vector x (x). To input the predictor z, one can use either the mean and standard deviation of z (mean.z and sd.z), or a specific vector z (z).

Note

Sometimes some of the regression lines are outside the default scope of the coordinates and thus cannot be seen; in such situations, one needs to, by entering additional arguments, adjust the scope to let proper sections of regression lines be seen. Refer to examples below for more details.

mediation

Effect sizes and confidence intervals in a mediation model

Description

Automate the process of simple mediation analysis (one independent variable and one mediator) and effect size estimation for mediation models, as discussed in Preacher and Kelley (2010).

Usage

```
mediation(x, mediator, dv, S = NULL, N = NULL, x.location.S = NULL,
mediator.location.S = NULL, dv.location.S = NULL, mean.x = NULL,
mean.m = NULL, mean.dv = NULL, conf.level = 0.95,
bootstrap = FALSE, B = 1000)
```

Arguments

<code>x</code>	vector of the predictor/independent variable
<code>mediator</code>	vector of the mediator variable
<code>dv</code>	vector of the dependent/outcome variable
<code>S</code>	Covariance matrix
<code>N</code>	Sample size, necessary when a covariance matrix (<code>S</code>) is used
<code>x.location.S</code>	location of the predictor/independent variable in the covariance matrix (<code>S</code>)
<code>mediator.location.S</code>	location of the mediator variable in the covariance matrix (<code>S</code>)
<code>dv.location.S</code>	location of the dependent/outcome variable in the covariance matrix (<code>S</code>)
<code>mean.x</code>	mean of the <code>x</code> (independent/predictor) variable when a covariance matrix (<code>S</code>) is used
<code>mean.m</code>	mean of the <code>m</code> (mediator) variable when a covariance matrix (<code>S</code>) is used
<code>mean.dv</code>	mean of the <code>y/dv</code> (dependent/outcome) variable when a covariance matrix (<code>S</code>) is used
<code>conf.level</code>	desired level of confidence (e.g., .90, .95, .99, etc.)
<code>bootstrap</code>	TRUE or FALSE, based on whether or not a bootstrap procedure is performed to obtain confidence intervals for the various effect sizes
<code>B</code>	number of bootstrap replications when <code>bootstrap=TRUE</code> (e.g., 10000)

Details

Based on the work of Preacher and Kelley (2010), this function implements (simple) mediation analysis in a way that automates much of the results that are generally of interest. More specifically, three regression outputs are automated as is the calculation of effect sizes that are thought to be useful or potentially useful in the context of mediation. Much work on mediation models exists in the literature, which should be consulted for proper interpretation of the effect sizes, models, and meaning of results.

Value

<code>Y.on.X\$Regression.Table</code>	Regression table of Y conditional on X
<code>Y.on.X\$Model.Fit</code>	Summary of model fit for the regression of Y conditional on X
<code>M.on.X\$Regression.Table</code>	Regression table of X conditional on M

<code>M.on.X\$Model.Fit</code>	Summary of model fit for the regression of X conditional on M
<code>Y.on.X.and.M\$Regression.Table</code>	Regression table of Y conditional on X and M
<code>Y.on.X.and.M\$Model.Fit</code>	Summary of model fit for the regression of Y conditional on X and M
<code>Indirect.Effect</code>	the product of $\hat{a} \times \hat{b}$, where \hat{a} and \hat{b} are the estimated coefficients of the path from the independent variable to the mediator and the path from the mediator to the dependent variable
<code>Indirect.Effect.Partially.Standardized</code>	It is the indirect effect (see <code>Indirect.Effect</code> above) divided by the estimated standard deviation of Y (MacKinnon, 2008)
<code>Index.of.Mediation</code>	Index of mediation (indirect effect multiplied by the ratio of the standard deviation of X to the standard deviation of Y) (Preacher and Hayes, 2008)
<code>R2_4.5</code>	An index of explained variance see MacKinnon (2008, Eq. 4.5) for details
<code>R2_4.6</code>	An index of explained variance see MacKinnon (2008, Eq. 4.6) for details
<code>R2_4.7</code>	An index of explained variance see MacKinnon (2008, Eq. 4.7) for details
<code>Maximum.Possible.Mediation.Effect</code>	the maximum attainable value of the mediation effect (i.e., the indirect effect), in the direction of the observed indirect effect, that could have been observed, conditional on the sample variances and on the magnitudes of relationships among some of the variables
<code>ab.to.Maximum.Possible.Mediation.Effect_kappa.squared</code>	the proportion of the maximum possible indirect effect; Uses the indirect effect in the numerator with the maximum possible mediation effect in the denominator (Preacher & Kelley, 2010)
<code>Ratio.of.Indirect.to.Total.Effect</code>	ratio of the indirect effect to the total effect (Freedman, 2001); also known as mediation ratio (Ditlevsen, Christensen, Lynch, Damsgaard, & Keiding, 2005); in epidemiological research and as the relative indirect effect (Huang, Sivaganesan, Succop, & Goodman, 2004); often loosely interpreted as the relative indirect effect
<code>Ratio.of.Indirect.to.Direct.Effect</code>	ratio of the indirect effect to the direct effect (Sobel, 1982)
<code>Success.of.Surrogate.Endpoint</code>	Success of a surrogate endpoint (Buyse & Molenberghs, 1998)
<code>SOS</code>	shared over simple effects (SOS) index, which is the ratio of the variance in Y explained by both X and M divided by the variance in Y explained by X (Lindenberger & Potter, 1998)
<code>Residual.Based_Gamma</code>	A residual based index (Preacher & Kelley, 2010)
<code>Residual.Based.Standardized_gamma</code>	A residual based index that is standardized, where the scales of M and Y are removed by using standardized values of M and Y (Preacher & Kelley, 2010)

```

Bar plots of mediation effects

Description

Provides an effect bar plot in the context of simple mediation.

Usage

```
mediation.effect.bar.plot(x, mediator, dv,
  main = "Mediation Effect Bar Plot", width = 1, left.text.adj = 0,
  right.text.adj = 0, rounding = 3, file = "", save.pdf = FALSE,
  save.eps = FALSE, save.jpg = FALSE, ...)
```

Arguments

<code>x</code>	vector of the predictor/independent variable
<code>mediator</code>	vector of the mediator variable
<code>dv</code>	vector of the dependent/outcome variable
<code>main</code>	main title
<code>width</code>	width of bar, default 1
<code>left.text.adj</code>	for fine tuning left side text adjustment
<code>right.text.adj</code>	for fine tuning right side text adjustment
<code>rounding</code>	how to round so that the values displayed in the plot do not have too few or too many significant digits
<code>file</code>	file name of the plot to be saved (not necessary)
<code>save.pdf</code>	TRUE or FALSE if the produced figure should be saved as a PDF file
<code>save.eps</code>	TRUE or FALSE if the produced figure should be saved as an EPS file
<code>save.jpg</code>	TRUE or FALSE if the produced figure should be saved as a JPG file
<code>...</code>	optional additional specifications for nested functions

Details

Provides an effect bar for mediation (Bauer, Preacher, & Gil, 2006) may be used to plot the results of a mediation analysis compactly. Effect bars represent, in a single metric, the relative magnitudes of several values that are important for interpreting indirect effects. Preacher and Kelley (2010) discuss this plotting method also.

Value

Only a figure is returned

mediation.effect.plot

Visualizing mediation effects

Description

Create a mediation effect plot

Usage

```
mediation.effect.plot(x, mediator, dv, ylab = "Dependent Variable",
  xlab = "Mediator", main = "Mediation Effect Plot",
  pct.from.top.a = 0.05, pct.from.left.c = 0.05, arrow.length.a = 0.05,
  arrow.length.c = 0.05, legend.loc = "topleft", file = "", pch = 20,
  xlim = NULL, ylim = NULL, save.pdf = FALSE, save.eps = FALSE,
  save.jpg = FALSE, ...)
```

Arguments

x	vector of the predictor/independent variable
mediator	vector of the mediator variable
dv	vector of the dependent/outcome variable
ylab	y-axis title label
xlab	x-axis title label
main	main title label
pct.from.top.a	figure fine tuning adjustment
pct.from.left.c	figure fine tuning adjustment

arrow.length.a	figure fine tuning adjustment
arrow.length.c	figure fine tuning adjustment
legend.loc	specify the location of the legend
file	file name of the plot to be saved (not necessary)
pch	plotting character
xlim	limits for the x axis
ylim	limits for the y axis
save.pdf	TRUE or FALSE if the produced figure should be saved as a PDF file
save.eps	TRUE or FALSE if the produced figure should be saved as an EPS file
save.jpg	TRUE or FALSE if the produced figure should be saved as a JPG file
...	to incorporate options from interval functions

Details

Merrill (1994; see also MacKinnon, 2008; MacKinnon et al., 2007; Sy, 2004) presents a method that involves plotting the indirect effect as the vertical distance between two lines. Fritz and MacKinnon (2008) present a detailed exposition of this method too. Preacher and Kelley (2010) discuss this plotting method and implement their own code, which was also independently done as part of Fritz and MacKinnon (2008).

In this type of plot, the two horizontal lines correspond to the predicted values of Y regressed on X at the mean of X and at one unit above the mean of X. The distance between these two lines is thus \hat{c} . The two vertical lines correspond to predicted values of M regressed on X at the same two values of X. The distance between these lines is \hat{a} . The lines corresponding to the regression of Y on M (controlling for X) are plotted for the same two values of X.

Value

Only a figure is returned

Note

Requires raw data.

`power.density.equivalence.md`

Density for power of two one-sided tests procedure (TOST) for equivalence

Description

A function to calculate density for the power of the two one-sided tests procedure (TOST). (See package `equivalence`, function `tost`.)

Usage

```
power.density.equivalence.md(power_sigma, alpha = alpha, theta1 = theta1, theta2 =
```

Arguments

<code>power_sigma</code>	x-value for integration
<code>alpha</code>	alpha level for the 2 t-tests (usually $\alpha=0.05$). Confidence interval for full test is at level $(1-2*\alpha)$
<code>theta1</code>	lower limit of equivalence interval on appropriate scale (regular or log)
<code>theta2</code>	upper limit of equivalence interval on appropriate scale
<code>diff</code>	true difference (ratio on log scale) in treatment means on appropriate scale
<code>sigma</code>	$\sqrt{\text{error variance}}$ as fraction (root MSE from ANOVA, or coefficient of variation)
<code>n</code>	number of subjects per treatment (number of total subjects for crossover design)
<code>nu</code>	degrees of freedom for sigma

Value

`power_density`
density at `diff` for power of TOST: the probability that the confidence interval will lie within [`theta1`, `theta2`]

# theta1, theta2, and diff must be on that scale. That is, use log(.8), etc.
```

power.equivalence.md

Power of Two One-Sided Tests Procedure (TOST) for Equivalence

Description

A function to calculate the power of the two one-sided tests procedure (TOST). This is the probability that a confidence interval lies within a specified equivalence interval. (See package `equivalence`, function `tost`.)

Usage

```
power.equivalence.md(alpha, logscale, ltheta1, ltheta2, ldiff, sigma, n, nu)
```

Arguments

alpha	<i>alpha</i> level for the 2 t-tests (usually <i>alpha</i> =0.05). Confidence interval for full test is at level $1 - 2 * \alpha$
logscale	whether to use logarithmic scale TRUE or not FALSE
ltheta1	lower limit of equivalence interval
ltheta2	upper limit of equivalence interval
ldiff	true difference (ratio on log scale) in treatment means
sigma	$\sqrt{\text{error variance}}$ as fraction (root MSE from ANOVA, or coefficient of variation)
n	number of subjects per treatment (number of total subjects for crossover design)
nu	degrees of freedom for sigma

Value

power	Power of TOST; the probability that the confidence interval will lie within [<i>theta1</i> , <i>theta2</i>] given ' <i>sigma</i> ', ' <i>n</i> ', and ' <i>nu</i> '

```
# Suppose that two formulations of a drug are to be compared on
# the regular scale using a two-period crossover design, with
# theta1 = -0.20, theta2 = 0.20, rm{CV} = 0.20, the
# difference in the mean bioavailability is 0.05 (5 percent), and we choose
# n=24, corresponding to 22 degrees of freedom. We need to test
# bioequivalence at the 5 percent significance level, which corresponds to
# having a 90 percent confidence interval lying within (-0.20, 0.20). Then
# the power will be 0.8029678. This corresponds to Phillips (1990),
# Table 1, 5th row, 5th column, and Figure 3. Use
```

```
power.equivalence.md(.05, FALSE, -.2, .2, .05, .20, 24, 22)

# If the formulations are compared on the logarithmic scale with
# theta1 = 0.80, theta2 = 1.25, n=18 (16 degrees of freedom), and
# a ratio of test to reference of 1.05. Then the power will be 0.7922796.
# This corresponds to Diletti, Table 1, power=.80, CV=.20, ratio=1.05, and Figure 1c. Use

power.equivalence.md(.05, TRUE, .8, 1.25, 1.05, .20, 18, 16)
```

```
power.equivalence.md.plot
      Plot power of Two One-Sided Tests Procedure (TOST) for Equivalence
```

Description

A function to plot the power of the two one-sided tests procedure (TOST) for various alternatives.

Usage

```
power.equivalence.md.plot(alpha, logscale, theta1, theta2, sigma, n, nu, title2)
```

Arguments

alpha	<i>alpha</i> level for the 2 t-tests (usually <i>alpha</i> =0.05). Confidence interval for full test is at level $1 - 2 * \alpha$
logscale	whether to use logarithmic scale TRUE or not FALSE
theta1	lower limit of equivalence interval
theta2	upper limit of equivalence interval
sigma	sqrt(error variance) as fraction (root MSE from ANOVA, or coefficient of variation)
n	number of subjects per treatment (number of total subjects for crossover design)
nu	degrees of freedom for sigma
title2	Title appearing at bottom of plot

Value

power Plot of power of TOST (probability that $(1 - 2 * \alpha)$ confidence interval will lie within (θ_1, θ_2) given sigma, n, and nu. Also returns matrix of 201 differences between θ_1 and θ_2 as first column, and power values corresponding to n for other columns.

`prof.salary`*Cohen et. al. (2003)'s professor salary data set*

Description

The data set of the salaries and other information of 62 some professors in Cohen et. al. (2003, pp. 81-82).

Usage

```
data (prof.salary)
```

Format

A data frame with 62 observations on the following 6 variables.

`id` the identification number

`time` the time since getting the Ph.D. degree

`pub` the number of publications

`sex` the gender, 1 for female and 0 for male

`citation` the citation count

`salary` the professor's current salary

`s.u`*Unbiased estimate for the standard deviation*

Description

Transforms the usual (and biased) estimate of the standard deviation into an unbiased estimator.

Usage

```
s.u(s=NULL, N=NULL, X=NULL)
```

Arguments

<code>s</code>	the usual estimate of the standard deviation (i.e., the square root of the unbiased estimate of the variance)
<code>N</code>	sample size <code>s</code> is based
<code>X</code>	vector of scores in which the unbiased estimate of the standard deviation should be calculated

Details

Returns the unbiased estimate for the standard deviation.

Value

The unbiased estimate for the standard deviation.

Examples

```
set.seed(113)
X <- rnorm(10, 100, 15)

# Square root of the unbiased estimate of the variance (not unbiased)
var(X)^.5

# One way to implement the function.
s.u(s=var(X)^.5, N=length(X))

# Another way to implement the function.
s.u(X=X)
```

Sigma.2.SigmaStar *Construct a covariance matrix with specified error of approximation*

Description

This function implements Cudeck & Browne's (1992) method to construct a covariance matrix in the structural equation modeling (SEM) context. Given an SEM model and its model parameters, a covariance matrix is obtained so that (a) the population discrepancy due to approximation equals a certain specified value; and (b) the population model parameter vector is the minimizer of the discrepancy function.

Usage

```
Sigma.2.SigmaStar(model, model.par, latent.var, discrep, ML = TRUE)
```

Arguments

<code>model</code>	an RAM (reticular action model; e.g., McArdle & McDonald, 1984) specification of a structural equation model, and should be of class <code>mod</code> . The model is specified in the same manner as does the <code>sem</code> package; see <code>sem</code> and <code>specify.model</code> for detailed documentations about model specifications in the RAM notation.
<code>model.par</code>	a vector containing the model parameters. The names of the elements in <code>theta</code> must be the same as the names of the model parameters specified in <code>model</code> .
<code>latent.var</code>	a vector containing the names of the latent variables
<code>discrep</code>	the desired discrepancy function minimum value
<code>ML</code>	the discrepancy function to be used, if <code>ML=TRUE</code> then the discrepancy function is based on normal theory maximum likelihood

Details

This function constructs a covariance matrix Σ^* such that $\Sigma^* = \Sigma(\theta) + E$, where $\Sigma(\theta)$ is the population model-implied covariance matrix, and E is a matrix containing the errors due to approximation. The matrix E is chosen so that the discrepancy function $F(\Sigma^*, \Sigma(\theta))$ has the specified discrepancy value.

This function uses the same notation to specify SEM models as does `sem`. Please refer to `sem` for more detailed documentation about model specification and the RAM notation. For technical discussion on how to obtain the model implied covariance matrix in the RAM notation given model parameters, see McArdle and McDonald (1984).

Value

<code>Sigma.star</code>	the population covariance matrix of manifest variables
<code>Sigma_theta</code>	the population model-implied covariance matrix
<code>E</code>	the matrix containing the population errors of approximation, i.e., <code>Sigma.star - Sigma_theta</code>

signal.to.noise.R2 *Signal to noise using squared multiple correlation coefficient*

Description

Function that calculates five different signal-to-noise ratios using the squared multiple correlation coefficient.

Usage

```
signal.to.noise.R2(R.Square, N, p)
```

Arguments

R.Square	usual estimate of the squared multiple correlation coefficient (with no adjustments)
N	sample size
p	number of predictors

Details

The method of choice is `phi2.UMVUE.NL`, but it requires p of 5 or more. In situations where $p < 5$, it is suggested that `phi2.UMVUE.L` be used.

Value

<code>phi2.hat</code>	Basic estimate of the signal-to-noise ratio using the usual estimate of the squared multiple correlation coefficient: $\text{phi2.hat} = R^2 / (1 - R^2)$
<code>phi2.adj.hat</code>	Estimate of the signal-to-noise ratio using the usual adjusted R Square in place of R Square: $\text{phi2.hat} = \text{Adj.R}^2 / (1 - \text{Adj.R}^2)$
<code>phi2.UMVUE</code>	Muirhead's (1985) unique minimum variance unbiased estimate of the signal-to-noise ratio (Muirhead uses θ -U): see reference or code for formula

`phi2.UMVUE.L` Muirhead's (1985) unique minimum variance unbiased linear estimate of the signal-to-noise ratio (Muirhead uses θ -L): see reference or code for formula

`phi2.UMVUE.NL`

Muirhead's (1985) unique minimum variance unbiased nonlinear estimate of the signal-to-noise ratio (Muirhead uses θ -NL); requires the number of predictors to be greater than five: see reference or code for formula

signal.to.noise.R2(R.Square=.5, N=50, p=5)
signal.to.noise.R2(R.Square=.5, N=100, p=2)
signal.to.noise.R2(R.Square=.5, N=100, p=5)
```

smd

Standardized mean difference

Description

Function to calculate the standardized mean difference (regular or unbiased) using either raw data or summary measures.

Usage

```
smd(Group.1 = NULL, Group.2 = NULL, Mean.1 = NULL, Mean.2 = NULL,
s.1 = NULL, s.2 = NULL, s = NULL, n.1 = NULL, n.2 = NULL,
Unbiased=FALSE)
```

Arguments

Group.1	Raw data for group 1.
Group.2	Raw data for group 2.
Mean.1	The mean of group 1.
Mean.2	The mean of group 2.
s.1	The standard deviation of group 1 (i.e., the square root of the unbiased estimator of the population variance).
s.2	The standard deviation of group 2 (i.e., the square root of the unbiased estimator of the population variance).
s	The pooled group standard deviation (i.e., the square root of the unbiased estimator of the population variance).
n.1	The sample size within group 1.
n.2	The sample size within group 2.
Unbiased	Returns the unbiased estimate of the standardized mean difference.

Details

When `Unbiased=TRUE`, the unbiased estimate of the standardized mean difference is returned (Hedges, 1981).

Value

Returns the estimated standardized mean difference.

```

smd.c

Standardized mean difference using the control group as the basis of standardization

Description

Function to calculate the standardized mean difference (regular or unbiased) using the control group standard deviation as the basis of standardization (for either raw data or summary measures).

Usage

```
smd.c(Group.T = NULL, Group.C = NULL, Mean.T = NULL, Mean.C = NULL,
s.C = NULL, n.C = NULL, Unbiased=FALSE)
```

Arguments

Group.T	Raw data for the treatment group.
Group.C	Raw data for the control group.
Mean.T	The mean of the treatment group.
Mean.C	The mean of the control group.

s.c	The standard deviation of the control group (i.e., the square root of the unbiased estimator of the population variance).
n.c	The sample size of the control group.
Unbiased	Returns the unbiased estimate of the standardized mean difference using the standard deviation of the control group.

Details

When `Unbiased=TRUE`, the unbiased estimate of the standardized mean difference (using the control group as the basis of standardization) is returned (Hedges, 1981). Although the unbiased estimate of the standardized mean difference is not often reported, at least at the present time, it is nevertheless made available to those who are interested in calculating this quantity.

Value

Returns the estimated standardized mean difference using the control group standard deviation as the basis of standardization.

 ss.aipe.c

Sample size planning for an ANOVA contrast from the Accuracy in Parameter Estimation (AIPE) perspective

Description

A function to calculate the appropriate sample size per group for the (unstandardized) ANOVA contrast so that the width of the confidence interval is sufficiently narrow.

Usage

```
ss.aipe.c(error.variance = NULL, c.weights, width, conf.level = 0.95,
assurance = NULL, certainty = NULL, MSwithin = NULL, SD = NULL, ...)
```

Arguments

error.variance	the common error variance; i.e., the mean square error
c.weights	the contrast weights
width	the desired full width of the obtained confidence interval
conf.level	the desired confidence interval coverage, (i.e., 1 - Type I error rate)
assurance	parameter to ensure that the obtained confidence interval width is narrower than the desired width with a specified degree of certainty (must be NULL or between zero and unity)
certainty	an alias for assurance
MSwithin	an alias for error.variance
SD	the standard deviation of the common error in ANOVA model
...	allows one to potentially include parameter values for inner functions

Value

n	the necessary sample size <i>per group</i>
---	--

Note

Be sure to use the error variance and not its square root (i.e., the standard deviation of the errors).

Examples

```
# Suppose the population error variance of some three-group ANOVA model
# is believed to be 40. The researcher is interested in the difference
# between the mean of group 1 and the average of means of group 2 and 3.
# To plan the sample size so that, with 90 percent certainty, the
# obtained 95 percent full confidence interval width is no wider than 3:

ss.aipe.c(error.variance=40, c.weights=c(1, -0.5, -0.5), width=3, assurance=.90)
```

ss.aipe.c.ancova *Sample size planning for a contrast in randomized ANCOVA from the Accuracy in Parameter Estimation (AIPE) perspective*

Description

A function to calculate the appropriate sample size per group for the (unstandardized) contrast, in one-covariate randomized ANCOVA, so that the width of the confidence interval is sufficiently narrow.

Usage

```
ss.aipe.c.ancova(error.var.ancova = NULL, error.var.anova = NULL,
rho = NULL, c.weights, width, conf.level = 0.95,
assurance = NULL, certainty = NULL)
```

Arguments

error.var.ancova	the population error variance of the ANCOVA model (i.e., the mean square within of the ANCOVA model)
error.var.anova	the population error variance of the ANOVA model (i.e., the mean square within of the ANOVA model)
rho	the population correlation coefficient of the response and the covariate
c.weights	the contrast weights
width	the desired full width of the obtained confidence interval
conf.level	the desired confidence interval coverage, (i.e., 1 - Type I error rate)
assurance	parameter to ensure that the obtained confidence interval width is narrower than the desired width with a specified degree of certainty (must be NULL or between zero and unity)
certainty	an alias for assurance

Details

Either the error variance of the ANCOVA model or of the ANOVA model can be used to plan the appropriate sample size per group. When using the error variance of the ANOVA model to plan sample size, the correlation coefficient of the response and the covariate is also needed.

Value

n the necessary sample size *per group*

Author(s)

Ken Kelley (University of Notre Dame; <KKelley@ND.Edu>); Keke Lai <Lai.15@ND.Edu>

c.weights=c(1, -0.5, -0.5), width=3, assurance=.90)
```

```
ss.aipe.c.ancova.sensitivity
```

Sensitivity analysis for sample size planning for the (unstandardized) contrast in randomized ANCOVA from the Accuracy in Parameter Estimation (AIPE) Perspective

Description

Performs a sensitivity analysis when planning sample size from the Accuracy in Parameter Estimation (AIPE) Perspective for the (unstandardized) contrast in randomized ANCOVA design.

Usage

```
ss.aipe.c.ancova.sensitivity(true.error.var.ancova = NULL,
  est.error.var.ancova = NULL, true.error.var.anova = NULL,
  est.error.var.anova = NULL, rho, est.rho = NULL, G = 10000,
  mu.y, sigma.y, mu.x, sigma.x, c.weights, width,
  conf.level = 0.95, assurance = NULL, certainty=NULL)
```

Arguments

<code>true.error.var.ancova</code>	population error variance of the ANCOVA model
<code>est.error.var.ancova</code>	estimated error variance of the ANCOVA model
<code>true.error.var.anova</code>	population error variance of the ANOVA model (i.e., excluding the covariate)
<code>est.error.var.anova</code>	estimated error variance of the ANOVA model (i.e., excluding the covariate)
<code>rho</code>	population correlation coefficient of the response and the covariate
<code>est.rho</code>	estimated correlation coefficient of the response and the covariate
<code>G</code>	number of generations (i.e., replications) of the simulation
<code>mu.y</code>	vector that contains the response's population mean of each group
<code>sigma.y</code>	the population standard deviation of the response
<code>mu.x</code>	the population mean of the covariate
<code>sigma.x</code>	the population standard deviation of the covariate
<code>c.weights</code>	the contrast weights
<code>width</code>	the desired full width of the obtained confidence interval
<code>conf.level</code>	the desired confidence interval coverage, (i.e., 1 - Type I error rate)
<code>assurance</code>	parameter to ensure that the obtained confidence interval width is narrower than the desired width with a specified degree of certainty (must be NULL or between zero and unity)
<code>certainty</code>	an alias for assurance

Details

The arguments `mu.y`, `mu.x`, `sigma.y`, and `sigma.x` are used to generate random data in the simulations for the sensitivity analysis. The value of `mu.y` should be the same as the square root of `true.error.var.anova`

So far this function is based on one-covariate randomized ANCOVA design only. The argument `mu.x` should be a single number, because it is assumed that the population mean of the covariate is equal across groups in randomized ANCOVA.

Value

<code>Psi.obs</code>	the observed (unstandardized) contrast
<code>se.Psi</code>	the standard error of the observed (unstandardized) contrast
<code>se.Psi.restricted</code>	the standard error of the observed (unstandardized) contrast calculated by ignoring the covariate
<code>se.res.over.se.full</code>	the ratio of contrast's full standard error over the restricted one in each iteration
<code>width.obs</code>	full confidence interval width
<code>Type.I.Error</code>	Type I error happens in each iteration
<code>Type.I.Error.Upper</code>	Type I error happens in the upper end in each iteration
<code>Type.I.Error.Lower</code>	Type I error happens in the lower end in each iteration
<code>Type.I.Error</code>	percentage of Type I error happened in the entire simulation
<code>Type.I.Error.Upper</code>	percentage of Type I error happened in the upper end in the entire simulation
<code>Type.I.Error.Lower</code>	percentage of Type I error happened in the lower end in the entire simulation
<code>width.NARROWER.than.desired</code>	percentage of obtained widths that are narrower than the desired width
<code>Mean.width.obs</code>	mean width of the obtained full confidence intervals
<code>Median.width.obs</code>	median width of the obtained full confidence intervals
<code>Mean.se.res.vs.se.full</code>	the mean of the ratios of contrast's full standard error over the restricted one
<code>Psi.pop</code>	population (unstandardized) contrast
<code>Contrast.Weights</code>	contrast weights
<code>mu.y</code>	the response's population mean of each group
<code>mu.x</code>	the population mean of the covariate
<code>sigma.x</code>	the population standard deviation of the covariate
<code>Sample.Size.per.Group</code>	sample size per group
<code>conf.level</code>	the desired confidence interval coverage, (i.e., 1 - Type I error rate)
<code>assurance</code>	specified assurance
<code>rho</code>	population correlation coefficient of the response and the covariate
<code>est.rho</code>	estimated correlation coefficient of the response and the covariate
<code>true.error.var.ANOVA</code>	population error variance of the ANOVA model
<code>est.error.var.ANOVA</code>	estimated error variance of the ANOVA model

ss.aipe.cv

Sample size planning for the coefficient of variation given the goal of Accuracy in Parameter Estimation approach to sample size planning

Description

Determines the necessary sample size so that the expected confidence interval width for the coefficient of variation will be sufficiently narrow, optionally with a desired degree of certainty that the interval will not wider than desired.

Usage

```
ss.aipe.cv(C.of.V = NULL, width = NULL, conf.level = 0.95,
degree.of.certainty = NULL, assurance=NULL, certainty=NULL,
mu = NULL, sigma = NULL, alpha.lower = NULL, alpha.upper = NULL,
Suppress.Statement = TRUE, sup.int.warns = TRUE, ...)
```

Arguments

C.of.V	population coefficient of variation which the sample size procedure is based
width	desired (full) width of the confidence interval
conf.level	confidence interval coverage; 1-Type I error rate
degree.of.certainty	value with which confidence can be placed that describes the likelihood of obtaining a confidence interval less than the value specified (e.g., .80, .90, .95)
assurance	an alias for degree.of.certainty
certainty	an alias for degree.of.certainty
mu	population mean (specified with sigma when C.of.V is not specified)

```

sigma          population standard deviation (specified with mu when C.of.V) is not speci-
               fied)
alpha.lower    Type I error for the lower confidence limit
alpha.upper    Type I error for the upper confidence limit
Suppress.Statement
               Suppress a message restating the input specifications
sup.int.warns  suppress internal function warnings (e.g., warnings associated with qt)
...           for modifying parameters of functions this function calls

```

Value

Returns the necessary sample size given the input specifications.

# Ensuring that the confidence interval will be sufficiently narrow with a 99%
# certainty for the situation above.
ss.aipe.cv(C.of.V=.1, width=.1, conf.level=.99, degree.of.certainty=.99)

```

```
ss.aipe.cv.sensitivity
```

*Sensitivity analysis for sample size planning given the Accuracy in
Parameter Estimation approach for the coefficient of variation.*

Description

Performs sensitivity analysis for sample size determination for the coefficient of variation given a population coefficient of variation (or population mean and standard deviation) and goals for the sample size procedure. Allows one to determine the effect of being wrong when estimating the population coefficient of variation in terms of the width of the obtained (two-sided) confidence intervals.

Usage

```
ss.aipe.cv.sensitivity(True.C.of.V = NULL, Estimated.C.of.V = NULL,
width = NULL, degree.of.certainty = NULL, assurance=NULL, certainty=NULL,
mean = 100, Specified.N = NULL, conf.level = 0.95,
G = 1000, print.iter = TRUE)
```

Arguments

<code>True.C.of.V</code>	population coefficient of variation
<code>Estimated.C.of.V</code>	estimated coefficient of variation
<code>width</code>	desired confidence interval width
<code>degree.of.certainty</code>	parameter to ensure confidence interval width with a specified degree of certainty (must be NULL or between zero and unity)
<code>assurance</code>	the alias for <code>degree.of.certainty</code>
<code>certainty</code>	an alias for <code>degree.of.certainty</code>
<code>mean</code>	Some arbitrary value that the simulation uses to generate data (the variance of the data is determined by the mean and the coefficient of variation)
<code>Specified.N</code>	selected sample size to use in order to determine distributional properties of at a given value of sample size (not used with <code>Estimated.C.of.V</code>)
<code>conf.level</code>	the desired degree of confidence (i.e., 1-Type I error rate).
<code>G</code>	number of generations (i.e., replications) of the simulation
<code>print.iter</code>	to print the current value of the iterations

Details

For sensitivity analysis when planning sample size given the desire to obtain narrow confidence intervals for the population coefficient of variation. Given a population value and an estimated value, one can determine the effects of incorrectly specifying the population coefficient of variation (`True.C.of.V`) on the obtained widths of the confidence intervals. Also, one can evaluate the percent of the confidence intervals that are less than the desired width (especially when modifying the `degree.of.certainty` parameter); see `ss.aipe.cv`

Alternatively, one can specify `Specified.N` to determine the results at a particular sample size (when doing this `Estimated.C.of.V` cannot be specified).

Value

<code>Data.from.Simulation</code>	list of the results in matrix form
<code>Specifications</code>	specification of the function
<code>Summary.of.Results</code>	summary measures of some important descriptive statistics

Note

Returns three lists, where each list has multiple components.

ss.aipe.pcm	<i>Sample size planning for polynomial change models in longitudinal study</i>
-------------	--

Description

This function plans sample size with respect to the group-by-time interaction in the context of a longitudinal design with two groups. It plans sample size from the accuracy in parameter estimation (AIPE) perspective, where the goal is to obtain a sufficiently narrow confidence interval for the fixed effect polynomial change coefficient parameter (e.g., linear, quadratic, etc.). The sample size returned can be one such that (a) the expected confidence interval width is sufficiently narrow, or (b) the observed confidence interval will be sufficiently narrow with a specified high degree of assurance (e.g., .99, .95, .90, etc.). This function accompanies Kelley and Rausch (2011).

Usage

```
ss.aipe.pcm(true.variance.trend, error.variance,
variance.true.minus.estimated.trend = NULL, duration, frequency,
width, conf.level = 0.95, trend = "linear", assurance = NULL)
```

Arguments

true.variance.trend	The variance of the individuals' true change coefficients (i.e., $\sigma_{v_m}^2$ in Kelley & Rausch, 2011) for the polynomial trend (e.g., linear, quadratic, etc.) of interest.
error.variance	The true error variance (i.e., σ_ϵ^2 in Kelley & Rausch, 2011).
variance.true.minus.estimated.trend	The variance of the difference between the m th true change coefficient minus the m th estimated change coefficient (i.e., $\sigma_{\hat{\pi}_m - \pi_m}^2$ from Equation 19 in Kelley & Rausch, 2011).
duration	The duration of the study.
frequency	The number of times measurement occurs within each unit of time.
width	width of the confidence interval

conf.level	The desired level of confidence for the confidence interval that will be computed at the completion of the study.
trend	The polynomial trend (1st-3rd) of interest specified as "linear", "quadratic", or "cubic".
assurance	Value with which confidence can be placed that describes the likelihood of obtaining a confidence interval less than the value specified (e.g, .80, .90, .95)

Value

Returns the necessary sample size for the combination of the desired goals and values of the population parameters for a specific design.

Note

Like in all formal sample size planning methods that require the value of one or more population parameter(s), if the population parameters are incorrectly specified, there is no guarantee that the sample size this function returns will be accurate. Of course, the further away from the true values, the further away the true sample size will tend to be.

The number of timepoints in a study (say M) is defined by $f \times D + 1$, where f is the frequency and D is the duration.

Examples

```
## Not run:
# An example used in Kelley and Rausch for the expected confidence interval
# width (returns 278). Thus, a necessary sample size of 278 is required when
# the duration of the study will be 4 units and the frequency of measurement
# occasions is 1 year in order for the expected confidence interval
# width to be 0.025 units.

ss.aipe.pcm(true.variance.trend=0.003, error.variance=0.0262, duration=4,
frequency=1, width=0.025, conf.level=.95)

# Now, when incorporating an assurance parameter (returns 316).
# Thus, a necessary sample size of 316 will ensure that the 95% confidence
# interval will be sufficiently narrow (i.e., have a width less than .025 units)
# at least 99% of the time.
ss.aipe.pcm(true.variance.trend=.003, error.variance=.0262, duration=4,
frequency=1, width=.025, conf.level=.95, assurance=.99)

## End(Not run)
```

 ss.aipe.R2

Sample Size Planning for Accuracy in Parameter Estimation for the multiple correlation coefficient.

Description

Determines necessary sample size for the multiple correlation coefficient so that the confidence interval for the population multiple correlation coefficient is sufficiently narrow. Optionally, there is a certainty parameter that allows one to be a specified percent certain that the observed interval will be no wider than desired.

Usage

```
ss.aipe.R2(Population.R2 = NULL, conf.level = 0.95, width = NULL,
Random.Predictors = TRUE, Random.Regressors, which.width = "Full", p = NULL,
K, degree.of.certainty = NULL, assurance=NULL, certainty=NULL,
verify.ss = FALSE, Tol = 1e-09, ...)
```

Arguments

Population.R2	value of the population multiple correlation coefficient
conf.level	confidence interval level (e.g., .95, .99, .90); 1-Type I error rate
width	width of the confidence interval (see which.width)
Random.Predictors	whether or not the predictor variables are random (set to TRUE) or are fixed (set to FALSE)
Random.Regressors	an alias for Random.Predictors; Random.Regressors overrides Random.Predictors
which.width	defines the width that width refers to
p	the number of predictor variables
K	an alias for p; K overrides p
degree.of.certainty	value with which confidence can be placed that describes the likelihood of obtaining a confidence interval less than the value specified (e.e.g. .80, .90, .95)
assurance	an alias for degree.of.certainty
certainty	an alias for degree.of.certainty
verify.ss	evaluates numerically via an internal Monte Carlo simulation the exact sample size given the specifications
Tol	the tolerance of the iterative function conf.limits.nct for convergence
...	for modifying the parameters of functions this function calls upon

Details

This function determines a necessary sample size so that the expected confidence interval width for the squared multiple correlation coefficient is sufficiently

narrow (when `degree.of.certainty=NULL`) so that the obtained confidence interval is no larger than the value specified with some desired degree of certainty (i.e., a probability that the obtained width is less than the specified width). The method depends on whether or not the regressors are regarded as fixed or random. This is the case because the distribution theory for the two cases is different and thus the confidence interval procedure is conditional the type of regressors. The default methods are approximate but can be made exact with the specification of `verify.ss=TRUE`, which performs an a priori Monte Carlo simulation study. Kelley (2007) and Kelley & Maxwell (2008) detail the methods used in the function, with the former focusing on random regressors and the latter on fixed regressors.

It is recommended that the option `verify.ss` should always be used! Doing so uses the method implied sample size as an estimate and then evaluates with an internal Monte Carlo simulation (i.e., via "brute-force" methods) the exact sample size given the goals specified. When `verify.ss=TRUE`, the default number of iterations is 10,000 but this can be changed by specifying `G=5000` (or some other value; 10000 is the recommended) When `verify.ss=TRUE` is specified, an internal function `verify.ss.aipe.R2` calls upon the `ss.aipe.R2.sensitivity` function for purposes of the internal Monte Carlo simulation study. See the `verify.ss.aipe.R2` function for arguments that can be passed from `ss.aipe.R2` to `verify.ss.aipe.R2`.

Value

`Required.Sample.Size`

sample size that should be used given the conditions specified.

Note

This function without `verify.SS=FALSE` can be slow to converge when `verify.SS=TRUE`, the function can take some time to converge (e.g., 15 minutes). Most times this will not be the case, but it is possible in some situations.

ss.aipe.R2.sensitivity

*Sensitivity analysis for sample size planning with the goal of Accuracy
in Parameter Estimation (i.e., a narrow observed confidence interval)*

Description

Given `Estimated.R2` and `True.R2`, one perform a sensitivity analysis to determine the effect of a misspecified population squared multiple correlation coefficient using the Accuracy in Parameter Estimation (AIPE) approach to sample size planning. The function evaluates the effect of a misspecified `True.R2` on the width of obtained confidence intervals.

Usage

```
ss.aipe.R2.sensitivity(True.R2 = NULL, Estimated.R2 = NULL, w = NULL,
p = NULL, Random.Predictors=TRUE, Selected.N=NULL,
degree.of.certainty = NULL, assurance=NULL, certainty=NULL,
conf.level = 0.95, Generate.Random.Predictors=TRUE, rho.yx = 0.3,
rho.xx = 0.3, G = 10000, print.iter = TRUE, ...)
```

Arguments

<code>True.R2</code>	value of the population squared multiple correlation coefficient
<code>Estimated.R2</code>	value of the estimated (for sample size planning) squared multiple correlation coefficient
<code>w</code>	full confidence interval width of interest
<code>p</code>	number of predictors
<code>Random.Predictors</code>	whether or not the sample size procedure and the simulation itself should be based on random (set to TRUE) or fixed predictors (set to FALSE)
<code>Selected.N</code>	selected sample size to use in order to determine distributional properties of at a given value of sample size
<code>degree.of.certainty</code>	parameter to ensure confidence interval width with a specified degree of certainty
<code>assurance</code>	an alias for <code>degree.of.certainty</code>
<code>certainty</code>	an alias for <code>degree.of.certainty</code>
<code>conf.level</code>	confidence interval coverage (symmetric coverage)
<code>Generate.Random.Predictors</code>	specify whether the simulation should be based on random (default) or fixed regressors.
<code>rho.yx</code>	value of the correlation between y (dependent variable) and each of the x variables (independent variables)
<code>rho.xx</code>	value of the correlation among the x variables (independent variables)
<code>G</code>	number of generations (i.e., replications) of the simulation
<code>print.iter</code>	should the iteration number (between 1 and G) during the run of the function
<code>...</code>	for modifying parameters of functions this function calls upon

Details

When `Estimated.R2=True.R2`, the results are that of a simulation study when all assumptions are satisfied. Rather than specifying `Estimated.R2`, one can specify `Selected.N` to determine the results of a particular sample size (when doing this `Estimated.R2` cannot be specified).

The sample size estimation procedure technically assumes multivariate normal variables ($p+1$) with fixed predictors (x /independent variables), yet the function assumes random multivariate normal predictors (having a $p+1$ multivariate distribution). As Gatsonis and Sampson (1989) note in the context of statistical power analysis (recall this function is used in the context of precision), there is little difference in the outcome.

In the behavioral, educational, and social sciences, predictor variables are almost always random, and thus `Random.Predictors` should generally be used. `Random.Predictors=TRUE` specifies how both the sample size planning procedure and the confidence intervals are calculated based on the random predictors/regressors. The internal simulation generates random or fixed predictors/regressors based on whether variables predictor variables are random or fixed. However, when `Random.Predictors=FALSE`, only the sample size planning procedure and the confidence intervals are calculated based on the parameter. The parameter `Generate.Random.Predictors` (where the default is `TRUE` so that random predictors/regressors are generated) allows random or fixed predictor variables to be generated. Because the sample size planning procedure and the internal simulation are both specified, for purposes of sensitivity analysis random/fixed can be crossed to examine the effects of specifying sample size based on one but using it on data based on the other.

Value

<code>Results</code>	a list containing vectors of the empirical results
<code>Specifications</code>	outputs the input specifications and required sample size
<code>Summary</code>	summary values for the results of the sensitivity analysis (simulation study)

ss.aipe.rc	<i>sample size necessary for the accuracy in parameter estimation approach for an unstandardized regression coefficient of interest</i>
------------	---

Description

A function used to plan sample size from the accuracy in parameter estimation perspective for an unstandardized regression coefficient of interest given the input specification.

Usage

```
ss.aipe.rc(Rho2.Y_X = NULL, Rho2.k_X.without.k = NULL,
K = NULL, b.k = NULL, width, which.width = "Full", sigma.Y = 1,
sigma.X.k = 1, RHO.XX = NULL, Rho.YX = NULL, which.predictor = NULL,
alpha.lower = NULL, alpha.upper = NULL, conf.level = .95,
degree.of.certainty = NULL, assurance=NULL, certainty=NULL,
Suppress.Statement = FALSE)
```

Arguments

Rho2.Y_X	Population value of the squared multiple correlation coefficient
Rho2.k_X.without.k	Population value of the squared multiple correlation coefficient predicting the k th predictor variable from the remaining $K-1$ predictor variables
K	the number of predictor variables
b.k	the regression coefficient for the k th predictor variable (i.e., the predictor of interest)
width	the desired width of the confidence interval
which.width	which width ("Full", "Lower", or "Upper") the width refers to (at present, only "Full" can be specified)
sigma.Y	the population standard deviation of Y (i.e., the dependent variables)
sigma.X.k	the population standard deviation of the k th X variable (i.e., the predictor variable of interest)
RHO.XX	Population correlation matrix for the p predictor variables
Rho.YX	Population K length vector of correlation between the dependent variable (Y) and the K independent variables

<code>which.predictor</code>	identifies which of the K predictors is of interest
<code>alpha.lower</code>	Type I error rate for the lower confidence interval limit
<code>alpha.upper</code>	Type I error rate for the upper confidence interval limit
<code>conf.level</code>	desired level of confidence for the computed interval (i.e., 1 - the Type I error rate)
<code>degree.of.certainty</code>	degree of certainty that the obtained confidence interval will be sufficiently narrow
<code>assurance</code>	an alias for <code>degree.of.certainty</code>
<code>certainty</code>	an alias for <code>degree.of.certainty</code>
<code>Suppress.Statement</code>	TRUE/FALSE statement whether or not a sentence describing the situation defined is printed with the necessary sample size

Details

Not all of the arguments need to be specified, only those that provide all of the necessary information so that the sample size can be determined for the conditions specified.

Value

Returns the necessary sample size in order for the goals of accuracy in parameter estimation to be satisfied for the confidence interval for a particular regression coefficient given the input specifications.

Note

This function calls upon `ss.aipe.reg.coef` in MBESS but has a different naming scheme. See `ss.aipe.reg.coef` for more details.

Examples

```
# Exchangable correlation structure
# Rho.YX <- c(.3, .3, .3, .3, .3)
# RHO.XX <- rbind(c(1, .5, .5, .5, .5), c(.5, 1, .5, .5, .5), c(.5, .5, 1, .5, .5),
# c(.5, .5, .5, 1, .5), c(.5, .5, .5, .5, 1))

# ss.aipe.rc(width=.1, which.width="Full", sigma.Y=1, sigma.X=1, RHO.XX=RHO.XX,
# Rho.YX=Rho.YX, which.predictor=1, conf.level=1-.05)

# ss.aipe.rc(width=.1, which.width="Full", sigma.Y=1, sigma.X=1, RHO.XX=RHO.XX,
# Rho.YX=Rho.YX, which.predictor=1, conf.level=1-.05, degree.of.certainty=.85)
```

```
ss.aipe.rc.sensitivity
```

Sensitivity analysis for sample size planing from the Accuracy in Parameter Estimation Perspective for the unstandardized regression coefficient

Description

Performs a sensitivity analysis when planning sample size from the Accuracy in Parameter Estimation Perspective for the unstandardized regression coefficient.

Usage

```
ss.aipe.rc.sensitivity(True.Var.Y = NULL, True.Cov.YX = NULL,
True.Cov.XX = NULL, Estimated.Var.Y = NULL, Estimated.Cov.YX = NULL,
Estimated.Cov.XX = NULL, Specified.N = NULL, which.predictor = 1,
w = NULL, Noncentral = FALSE, Standardize = FALSE, conf.level = 0.95,
degree.of.certainty = NULL, assurance=NULL, certainty=NULL,
G = 1000, print.iter = TRUE)
```

Arguments

<code>True.Var.Y</code>	Population variance of the dependent variable (Y)
<code>True.Cov.YX</code>	Population covariances vector between the p predictor variables and the dependent variable (Y)
<code>True.Cov.XX</code>	Population covariance matrix of the p predictor variables
<code>Estimated.Var.Y</code>	Estimated variance of the dependent variable (Y)
<code>Estimated.Cov.YX</code>	Estimated covariances vector between the p predictor variables and the dependent variable (Y)
<code>Estimated.Cov.XX</code>	Estimated Population covariance matrix of the p predictor variables

Specified.N	Directly specified sample size (instead of using Estimated.Rho.YX and Estimated.RHO.XX)
which.predictor	identifies which of the p predictors is of interest
w	desired confidence interval width for the regression coefficient of interest
Noncentral	specify with a TRUE/FALSE statement whether or not the noncentral approach to sample size planning should be used
Standardize	specify with a TRUE/FALSE statement whether or not the regression coefficient will be standardized; default is TRUE
conf.level	desired level of confidence for the computed interval (i.e., 1 - the Type I error rate)
degree.of.certainty	degree of certainty that the obtained confidence interval will be sufficiently narrow (i.e., the probability that the observed interval will be no larger than desired).
assurance	an alias for degree.of.certainty
certainty	an alias for degree.of.certainty
G	the number of generations/replication of the simulation student within the function
print.iter	specify with a TRUE/FALSE statement if the iteration number should be printed as the simulation within the function runs

Details

Direct specification of True.Rho.YX and True.RHO.XX is necessary, even if one is interested in a single regression coefficient, so that the covariance/correlation structure can be specified when the simulation student within the function runs.

Value

Results	a matrix containing the empirical results from each of the G replication of the simulation
Specifications	a list of the input specifications and the required sample size
Summary.of.Results	summary values for the results of the sensitivity analysis (simulation study) given the input specification

Note

Note that when True.Rho.YX=Estimated.Rho.YX and True.RHO.XX=Estimated.RHO.XX, the results are not literally from a sensitivity analysis, rather the function performs a standard simulation study. A simulation study can be helpful in order to determine if the sample size procedure under or overestimates necessary sample size.

See `ss.aipe.reg.coef.sensitivity` in MBESS for more details.

ss.aipe.reg.coef *sample size necessary for the accuracy in parameter estimation approach for a regression coefficient of interest*

Description

A function used to plan sample size from the accuracy in parameter estimation approach for a regression coefficient of interest given the input specification.

Usage

```
ss.aipe.reg.coef(Rho2.Y_X=NULL, Rho2.j_X.without.j=NULL, p=NULL,
b.j=NULL, width, which.width="Full", sigma.Y=1, sigma.X=1, RHO.XX=NULL,
Rho.YX=NULL, which.predictor=NULL, Noncentral=FALSE, alpha.lower=NULL,
alpha.upper=NULL, conf.level=.95, degree.of.certainty=NULL, assurance=NULL,
certainty=NULL, Suppress.Statement=FALSE)
```

Arguments

Rho2.Y_X	Population value of the squared multiple correlation coefficient
Rho2.j_X.without.j	Population value of the squared multiple correlation coefficient predicting the jth predictor variable from the remaining p-1 predictor variables
p	the number of predictor variables
b.j	the regression coefficient for the jth predictor variable (i.e., the predictor of interest)
width	the desired width of the confidence interval
which.width	which width ("Full", "Lower", or "Upper") the width refers to (at present, only "Full" can be specified)
sigma.Y	the population standard deviation of Y (i.e., the dependent variables)
sigma.X	the population standard deviation of the jth X variable (i.e., the predictor variable of interest)

RHO.XX	Population correlation matrix for the p predictor variables
Rho.YX	Population p length vector of correlation between the dependent variable (Y) and the p independent variables
which.predictor	identifies which of the p predictors is of interest
Noncentral	specify with a TRUE/FALSE statement whether or not the noncentral approach to sample size planning should be used
alpha.lower	Type I error rate for the lower confidence interval limit
alpha.upper	Type I error rate for the upper confidence interval limit
conf.level	desired level of confidence for the computed interval (i.e., 1 - the Type I error rate)
degree.of.certainty	degree of certainty that the obtained confidence interval will be sufficiently narrow
assurance	an alias for degree.of.certainty
certainty	an alias for degree.of.certainty
Suppress.Statement	TRUE/FALSE statement whether or not a sentence describing the situation defined is printed with the necessary sample size

Details

Not all of the arguments need to be specified, only those that provide all of the necessary information so that the sample size can be determined for the conditions specified.

Value

Returns the necessary sample size in order for the goals of accuracy in parameter estimation to be satisfied for the confidence interval for a particular regression coefficient given the input specifications.

# degree.of.certainty=NULL, Suppress.Statement=FALSE)

# ss.aipe.reg.coef(width=.1, which.width="Full", sigma.Y=1, sigma.X=1, RHO.XX=RHO.XX,
# Rho.YX=Rho.YX, which.predictor=1, Noncentral=TRUE, conf.level=1-.05,
# degree.of.certainty=.85, Suppress.Statement=FALSE)

```

```
ss.aipe.reg.coef.sensitivity
```

Sensitivity analysis for sample size planing from the Accuracy in Parameter Estimation Perspective for the (standardized and unstandardized) regression coefficient

Description

Performs a sensitivity analysis when planning sample size from the Accuracy in Parameter Estimation Perspective for the standardized or unstandardized regression coefficient.

Usage

```

ss.aipe.reg.coef.sensitivity(True.Var.Y = NULL, True.Cov.YX = NULL,
True.Cov.XX = NULL, Estimated.Var.Y = NULL, Estimated.Cov.YX = NULL,
Estimated.Cov.XX = NULL, Specified.N = NULL, which.predictor = 1,
w = NULL, Noncentral = FALSE, Standardize = FALSE, conf.level = 0.95,
degree.of.certainty = NULL, assurance=NULL, certainty=NULL,
G = 1000, print.iter = TRUE)

```

Arguments

True.Var.Y	Population variance of the dependent variable (Y)
True.Cov.YX	Population covariances vector between the p predictor variables and the dependent variable (Y)
True.Cov.XX	Population covariance matrix of the p predictor variables

<code>Estimated.Var.Y</code>	Estimated variance of the dependent variable (Y)
<code>Estimated.Cov.YX</code>	Estimated covariances vector between the p predictor variables and the dependent variable (Y)
<code>Estimated.Cov.XX</code>	Estimated Population covariance matrix of the p predictor variables
<code>Specified.N</code>	Directly specified sample size (instead of using <code>Estimated.Rho.YX</code> and <code>Estimated.RHO.XX</code>)
<code>which.predictor</code>	identifies which of the p predictors is of interest
<code>w</code>	desired confidence interval width for the regression coefficient of interest
<code>Noncentral</code>	specify with a TRUE/FALSE statement whether or not the noncentral approach to sample size planning should be used
<code>Standardize</code>	specify with a TRUE/FALSE statement whether or not the regression coefficient will be standardized
<code>conf.level</code>	desired level of confidence for the computed interval (i.e., 1 - the Type I error rate)
<code>degree.of.certainty</code>	degree of certainty that the obtained confidence interval will be sufficiently narrow
<code>assurance</code>	an alias for <code>degree.of.certainty</code>
<code>certainty</code>	an alias for <code>degree.of.certainty</code>
<code>G</code>	the number of generations/replication of the simulation student within the function
<code>print.iter</code>	specify with a TRUE/FALSE statement if the iteration number should be printed as the simulation within the function runs

Details

Direct specification of `True.Rho.YX` and `True.RHO.XX` is necessary, even if one is interested in a single regression coefficient, so that the covariance/correlation structure can be specified when the simulation student within the function runs.

Value

<code>Results</code>	a matrix containing the empirical results from each of the G replication of the simulation
<code>Specifications</code>	a list of the input specifications and the required sample size
<code>Summary.of.Results</code>	summary values for the results of the sensitivity analysis (simulation study) given the input specification

Note

Note that when $\text{True.Rho.YX}=\text{Estimated.Rho.YX}$ and $\text{True.RHO.XX}=\text{Estimated.RHO.XX}$, the results are not literally from a sensitivity analysis, rather the function performs a standard simulation study. A simulation study can be helpful in order to determine if the sample size procedure under or overestimates necessary sample size.

ss.aipe.reliability

Sample Size Planning for Accuracy in Parameter Estimation for reliability coefficients.

Description

This function determines a necessary sample size so that the expected confidence interval width for the alpha coefficient or omega coefficient is sufficiently narrow (when assurance=NULL) or so that the obtained confidence interval is no larger than the value specified with some desired degree of certainty (i.e., a probability that the obtained width is less than the specified width; assurance=.85). This function calculates coefficient alpha based on McDonald's (1999) formula for coefficient alpha, also known as Guttman-Cronbach alpha. It also uses coefficient omega from McDonald (1999). When the 'Parallel' or 'True Score' model is used, coefficient alpha is calculated. When the 'Congeneric' model is used, coefficient omega is calculated.

Usage

```
ss.aipe.reliability(model = NULL, type = NULL, width = NULL, S = NULL, conf.level =
```

Arguments

model	the type of measurement model (e.g., "parallel items", "true-score equivalent", or "congeneric model") for a homogeneous single common factor test
type	the type of method to base the formation of the confidence interval on, either the "Factor Analytic" (McDonald, 1999) or "Normal Theory" (van Zyl, Neudecker, & Nel, 2000)

width	the desired full width of the confidence interval
S	a symmetric covariance matrix
conf.level	the desired confidence interval coverage, (i.e., 1- Type I error rate)
assurance	parameter to ensure that the obtained confidence interval width is narrower than the desired width with a specified degree of certainty
data	the data set that the reliability coefficient is obtained from
i	number of items
cor.est	the estimated inter-item correlation
lambda	the vector of population factor loadings
psi.square	the vector of population error variances
initial.iter	the number of initial iterations or generations/replications of the simulation study within the function
final.iter	the number of final iterations or generations/replications of the simulation study
start.ss	the initial sample size to start the simulation at

Value

~Describe the value returned If it is a LIST, use

Required.Sample.Size	the necessary sample size
width	the specified full width of the confidence interval
specified.assurance	the specified degree of certainty
empirical.assurance	the empirical assurance based on the necessary sample size returned
final.iter	the specified number of iterations in the simulation study

Warning

In some conditions you may receive a warning, such as "In sem.default(ram = ram, S = S, N = N, param.names = pars, var.names = vars,;Could not compute QR decomposition of Hessian. Optimization probably did not converge." This indicates that the model likely did not converge. In certain conditions this may occur because the model is not being fit well due to small sample size, a low number of iterations, or a poorly behaved covariance matrix.

Note

Not all of the items can be entered into the function to represent the population values. For example, either 'data' can be used, or 'S', or 'i', 'cor.est', and 'psi.square', or 'i', 'lambda', and 'psi.square'. With a large number of iterations ('final.iter') this function may take a while to execute. Please be patient.

ss.aipe.rmsea

Sample size planning for RMSEA in SEM

Description

Sample size planning for the population root mean square error of approximation (RMSEA) from the accuracy in parameter estimation (AIPE) perspective. The sample size is planned so that the expected width of a confidence interval for the population RMSEA is no larger than desired.

Usage

```
ss.aipe.rmsea(RMSEA, df, width, conf.level = 0.95)
```

Arguments

RMSEA	the input RMSEA value
df	degrees of freedom of the model
width	desired confidence interval width
conf.level	desired confidence level (e.g., .90, .95, .99, etc.)

Value

Returns the necessary total sample size in order to achieve the desired degree of accuracy (i.e., the sufficiently narrow confidence interval).

```

```
ss.aipe.rmsea.sensitivity
      a priori Monte Carlo simulation for sample size planning for RMSEA
      in SEM
```

Description

Conduct a priori Monte Carlo simulation to empirically study the effects of (mis)specifications of input information on the calculated sample size. The sample size is planned so that the expected width of a confidence interval for the population RMSEA is no larger than desired. Random data are generated from the true covariance matrix but fit to the proposed model, whereas sample size is calculated based on the input covariance matrix and proposed model.

Usage

```
ss.aipe.rmsea.sensitivity(width, model, Sigma, N=NULL,
  conf.level=0.95, G=200, save.file="sim.results.txt", ...)
```

Arguments

<code>width</code>	desired confidence interval width for the model parameter of interest
<code>model</code>	the model the researcher proposes, may or may not be the true model. This argument should be an RAM (reticular action model; e.g., McArdle & McDonald, 1984) specification of a structural equation model, and should be of class <code>mod</code> . The model is specified in the same manner as does the <code>sem</code> package; see <code>sem</code> and <code>specify.model</code> for detailed documentation about model specifications in the RAM notation.
<code>Sigma</code>	the true population covariance matrix, which will be used to generate random data for the simulation study. The row names and column names of <code>Sigma</code> should be the same as the manifest variables in <code>model</code> .
<code>N</code>	if <code>N</code> is specified, random sample of the specified <code>N</code> size will be generated. Otherwise the sample size is calculated with the sample size planning method with the goal that the expected width of a confidence interval for population RMSEA is no larger than desired.
<code>conf.level</code>	confidence level (i.e., 1- Type I error rate)
<code>G</code>	number of replications in the Monte Carlo simulation
<code>save.file</code>	the name of the file that simulation results will be saved to
<code>...</code>	allows one to potentially include parameter values for inner functions

Details

This function implements the sample size planning methods proposed in Kelley and Lai (2010). It depends on the function `sem` in the `sem` package to fit the proposed model to random data, and uses the same notation to specify SEM models as does `sem`. Please refer to `sem` for more detailed documentation about model specifications, the RAM notation, and model fitting techniques. For technical discussion on how to obtain the model implied covariance matrix in the RAM notation given model parameters, see McArdle and McDonald (1984)

Value

<code>successful.replication</code>	the number of successful replications
<code>w</code>	the <code>G</code> random confidence interval widths
<code>RMSEA.hat</code>	the <code>G</code> estimated RMSEA values based on the <code>G</code> random samples
<code>sample.size</code>	the sample size calculated
<code>df</code>	degrees of freedom of the proposed model
<code>RMSEA.pop</code>	the input RMSEA value that is used to calculate the necessary sample size
<code>desired.width</code>	desired confidence interval width
<code>mean.width</code>	mean of the random confidence interval widths
<code>median.width</code>	median of the random confidence interval widths
<code>assurance</code>	the proportion of confidence interval widths narrower than desired

```

quantile.width      99, 97, 95, 90, 80, 70, and 60 percentiles of the random confidence interval
                    widths
alpha.upper         the upper empirical Type I error rate
alpha.lower         the lower empirical Type I error rate
alpha               total empirical Type I error rate
conf.level          confidence level
sim.results.txt     a text file that saves the simulation results; it updates after each replication.
                    'sim.results.txt' is the default file name

```

Note

Sometimes this function jumps out of the loop before it finishes the simulation. The reason is because the `sem` function that this function calls to fit the model fails to converge when searching for maximum likelihood estimates of model parameters. Since the results in previous replications are saved, the user can start this function again, and specify the number of replications (i.e., `G`) to be the desired total number of replications minus the number of previous successful replications.

#####
EXAMPLE 1
#####
# To replicate the simulation in the first panel, second column of
# Table 2 (i.e., population RMSEA=0.0268, df=23, desired width=0.02)
# in Lai and Kelley (2010), the following steps can be used.

```

```

## STEP 1: Obtain the (correct) population covariance matrix implied by Model 2
# This requires the model and its population model parameter values.
library(MASS)
library(sem)

# Specify Model 2 in the RAM notation
model.2<-specify.model()
x11 -> y1, lambda1, 1
x11 -> y2, NA, 1
x11 -> y3, lambda2, 1
x11 -> y4, lambda3, 0.3
eta1 -> y4, lambda4, 1
eta1 -> y5, NA, 1
eta1 -> y6, lambda5, 1
eta1 -> y7, lambda6, 0.3
eta2 -> y6, lambda7, 0.3
eta2 -> y7, lambda8, 1
eta2 -> y8, NA, 1
eta2 -> y9, lambda9, 1
x11 -> eta1, gamma11, 0.6
eta1 -> eta2, beta21, 0.6
x11 <-> x11, phi11, 0.49
eta1 <-> eta1, psi11, 0.3136
eta2 <-> eta2, psi22, 0.3136
y1 <-> y1, delta1, 0.51
y2 <-> y2, delta2, 0.51
y3 <-> y3, delta3, 0.51
y4 <-> y4, delta4, 0.2895
y5 <-> y5, delta5, 0.51
y6 <-> y6, delta6, 0.2895
y7 <-> y7, delta7, 0.2895
y8 <-> y8, delta8, 0.51
y9 <-> y9, delta9, 0.51

# To inspect the specified model
model.2

# Specify model parameter values
theta <- c(1, 1, 0.3, 1,1, 0.3, 0.3, 1, 1, 0.6, 0.6,
0.49, 0.3136, 0.3136, 0.51, 0.51, 0.51, 0.2895, 0.51, 0.2895, 0.2895, 0.51, 0.51)

names(theta) <- c("lambda1","lambda2","lambda3",
"lambda4","lambda5","lambda6","lambda7","lambda8","lambda9",
"gamma11", "beta21",
"phi11", "psi11", "psi22",
"delta1","delta2","delta3","delta4","delta5","delta6","delta7",
"delta8","delta9")

res<-theta.2.Sigma.theta(model=model.2, theta=theta,
latent.vars=c("x11", "eta1","eta2"))

Sigma.theta <- res$Sigma.theta

```

```

# Then 'Sigma.theta' is the (true) population covariance matrix

## STEP 2: Create a misspecified model
# The following model is misspecified in the same way as did Lai and Kelley (2010)
# with the goal to obtain a relatively small population RMSEA

model.2.mis<-specify.model()
xi1 -> y1, lambda1, 1
xi1 -> y2, NA, 1
xi1 -> y3, lambda2, 1
xi1 -> y4, lambda3, 0.3
eta1 -> y4, lambda4, 1
eta1 -> y5, NA, 1
eta1 -> y6, lambda5, 0.96
eta2 -> y6, lambda7, 0.33
eta2 -> y7, lambda8, 1.33
eta2 -> y8, NA, 1
eta2 -> y9, lambda9, 1
xi1 -> eta1, gamma11, 0.6
eta1 -> eta2, beta21, 0.65
xi1 <-> xi1, phi11, 0.49
eta1 <-> eta1, psi11, 0.3136
eta2 <-> eta2, psi22, 0.23
y1 <-> y1, delta1, 0.51
y2 <-> y2, delta2, 0.51
y3 <-> y3, delta3, 0.51
y4 <-> y4, delta4, 0.2895
y5 <-> y5, delta5, 0.51
y6 <-> y6, delta6, 0.29
y7 <-> y7, delta7, 0.22
y8 <-> y8, delta8, 0.56
y9 <-> y9, delta9, 0.56

# To verify the population RMSEA of this misspecified model
fit<-sem(ram=model.2.mis, S=Sigma.theta, N=1000000)
summary(fit)$RMSEA

## STEP 3: Conduct the simulation
# The number of replications is set to a very small value just to demonstrate
# and save time. Real simulation studies require a larger number (e.g., 500, 1,000)

ss.aipe.rmsea.sensitivity(width=0.02, model=model.2.mis, Sigma=Sigma.theta, G=10)

## STEP 3+: In cases where this function stops before it finishes the simulation
# Suppose it stops at the 7th replication. The text
# file "results_ss.aipe.rmsea.sensitivity.txt" saves the results in all
# previous replications; in this case it contains 6 replications since
# the simulation stopped at the 7th. The user can start this function again and specify
# 'G' to 4 (i.e., 10-6). New results will be appended to previous ones in the same file.

ss.aipe.rmsea.sensitivity(width=0.02, model=model.2.mis, Sigma=Sigma.theta, G=4)

```

```
#####
EXAMPLE 2
#####
# In addition to create a misspecified model by changing the model
# parameters in the true model as does Example 1, a misspecified
# model can also be created with the Cudeck-Browne (1992) procedure.
# This procedure is implemented in the 'Sigma.2.SigmaStar()' function in
# the MBESS package. Please refer to the help file of 'Sigma.2.SigmaStar()'
# for detailed documentation.

## STEP 1: Specify the model
# This model is the same as the model in the first step of Example 1, but the
# model-implied population covariance matrix is no longer the true population
# covariance matrix. The true population covariance matrix will be generated
# in Step 2 with the Cudeck-Browne procedure.
library(MASS)
library(sem)

model.2<-specify.model()
x11 -> y1, lambda1, 1
x11 -> y2, NA, 1
x11 -> y3, lambda2, 1
x11 -> y4, lambda3, 0.3
eta1 -> y4, lambda4, 1
eta1 -> y5, NA, 1
eta1 -> y6, lambda5, 1
eta1 -> y7, lambda6, 0.3
eta2 -> y6, lambda7, 0.3
eta2 -> y7, lambda8, 1
eta2 -> y8, NA, 1
eta2 -> y9, lambda9, 1
x11 -> eta1, gamma11, 0.6
eta1 -> eta2, beta21, 0.6
x11 <-> x11, phi11, 0.49
eta1 <-> eta1, psi11, 0.3136
eta2 <-> eta2, psi22, 0.3136
y1 <-> y1, delta1, 0.51
y2 <-> y2, delta2, 0.51
y3 <-> y3, delta3, 0.51
y4 <-> y4, delta4, 0.2895
y5 <-> y5, delta5, 0.51
y6 <-> y6, delta6, 0.2895
y7 <-> y7, delta7, 0.2895
y8 <-> y8, delta8, 0.51
y9 <-> y9, delta9, 0.51

theta <- c(1, 1, 0.3, 1,1, 0.3, 0.3, 1, 1, 0.6, 0.6,
0.49, 0.3136, 0.3136, 0.51, 0.51, 0.51, 0.2895, 0.51, 0.2895, 0.2895, 0.51, 0.51)

names(theta) <- c("lambda1","lambda2","lambda3",
"lambda4","lambda5","lambda6","lambda7","lambda8","lambda9",
```

```

"gamma11", "beta21",
"phi11", "psi11", "psi22",
"delta1", "delta2", "delta3", "delta4", "delta5", "delta6", "delta7",
"delta8", "delta9")

## STEP 2: Create the true population covariance matrix, so that (a) the model fits
# to this covariance matrix with specified discrepancy; (b) the population model
# parameters (the object 'theta') is the minimizer in fitting the model to the true
# population covariance matrix.

# Since the desired RMSEA is 0.0268 and the df is 22, the MLE discrepancy value
# is specified to be 22*0.0268*0.0268, given the definition of RMSEA.

res <- Sigma.2.SigmaStar(model=model.2, model.par=theta,
latent.var=c("xi1", "eta1", "eta2"), discrep=22*0.0268*0.0268)

Sigma.theta.star <- res$Sigma.star

# To verify that the population RMSEA is 0.0268
res2 <- sem(ram=model.2, S=Sigma.theta.star, N=1000000)
summary(res2)$RMSEA

## STEP 3: Conduct the simulation
# Note although Examples 1 and 2 have the same population RMSEA, the
# model df and true population covariance matrix are different. Example 1
# uses 'model.2.mis' and 'Sigma.theta', whereas Example 2 uses 'model.2'
# and 'Sigma.theta.star'. Since the df is different, it requires a different sample
# size to achieve the same desired confidence interval width.
ss.aipe.rmsea.sensitivity(width=0.02, model=model.2, Sigma=Sigma.theta.star, G=10)

## End(Not run)

```

ss.aipe.sc

*Sample size planning for Accuracy in Parameter Estimation (AIPE) of
the standardized contrast in ANOVA*

Description

A function to calculate the appropriate sample size per group for the standardized contrast in ANOVA such that the width of the confidence interval is sufficiently narrow.

Usage

```
ss.aipe.sc(psi, c.weights, width, conf.level = 0.95,
assurance = NULL, certainty = NULL, ...)
```

Arguments

psi	population standardized contrast
c.weights	the contrast weights

width	the desired full width of the obtained confidence interval
conf.level	the desired confidence interval coverage, (i.e., 1 - Type I error rate)
assurance	parameter to ensure that the obtained confidence interval width is narrower than the desired width with a specified degree of certainty (must be NULL or between zero and unity)
certainty	an alias for assurance
...	allows one to potentially include parameter values for inner functions

Value

n necessary sample size *per group*

# of 95 percent confidence interval of the standardized
# contrast is, with 90 percent assurance, no wider than .4:

# ss.aipe.sc(psi=.6, c.weights=c(.5, .5, -.5, -.5, 0), width=.4, assurance=.90)
```

ss.aipe.sc.ancova *Sample size planning from the AIPE perspective for standardized ANCOVA contrasts*

Description

Sample size planning from the accuracy in parameter estimation (AIPE) perspective for standardized ANCOVA contrasts.

Usage

```
ss.aipe.sc.ancova(Psi = NULL, sigma.anova = NULL, sigma.ancova = NULL,
psi = NULL, ratio = NULL, rho = NULL, divisor = "s.ancova",
c.weights, width, conf.level = 0.95, assurance = NULL, ...)
```

Arguments

Psi	the population unstandardized ANCOVA (adjusted) contrast
sigma.anova	the population error standard deviation of the ANOVA model
sigma.ancova	the population error standard deviation of the ANCOVA model
psi	the population standardized ANCOVA (adjusted) contrast
ratio	the ratio of sigma.ancova over sigma.anova
rho	the population correlation coefficient between the response and the covariate
divisor	which error standard deviation to be used in standardizing the contrast; the value can be either "s.ancova" or "s.anova"
c.weights	contrast weights
width	the desired full width of the obtained confidence interval
conf.level	the desired confidence interval coverage, (i.e., 1 - Type I error rate)
assurance	parameter to ensure that the obtained confidence interval width is narrower than the desired width with a specified degree of certainty (must be NULL or between zero and unity)
...	allows one to potentially include parameter values for inner functions

Details

The sample size planning method this function is based on is developed in the context of simple (i.e., one-response-one-covariate) ANCOVA model and randomized design (i.e., same population covariate mean across groups).

An ANCOVA contrast can be standardized in at least two ways: (a) divided by the error standard deviation of the ANOVA model, (b) divided by the error standard deviation of the ANCOVA model. This function can be used to analyze both types of standardized ANCOVA contrasts.

Not all of the arguments about the effect sizes need to be specified. If `divisor="s.ancova"` is used in the argument, then input either (a) `psi`, or (b) `Psi` and `s.ancova`. If `divisor="s.anova"` is used in the argument, possible specifications are (a) `Psi`, `s.ancova`, and `s.anova`; (b) `psi`, and `ratio`; (c) `psi`, and `rho`.

Value

This function returns the sample size *per group*.

Note

When `divisor="s.anova"` and the argument `assurance` is specified, the necessary sample size per group returned by the function with `assurance` specified is slightly underestimated. The method to obtain exact sample size in the above situation has not been developed yet. A practical solution is to use the sample size returned as the starting value to conduct a priori Monte Carlo simulations with function `ss.aipe.sc.ancova.sensitivity`, as discussed in Lai & Kelley (under review).

```
ss.aipe.sc.ancova.sensitivity
      Sensitivity analysis for the sample size planning method for standard-
      ized ANCOVA contrast
```

Description

Sensitivity analysis for the sample size planning method with the goal to obtain sufficiently narrow confidence intervals for standardized ANCOVA complex contrasts.

Usage

```
ss.aipe.sc.ancova.sensitivity(true.psi = NULL, estimated.psi = NULL,
c.weights, desired.width = NULL, selected.n = NULL, mu.x = 0,
sigma.x = 1, rho, divisor = "s.ancova", assurance = NULL,
conf.level = 0.95, G = 10000, print.iter = TRUE, detail = TRUE, ...)
```

Arguments

true.psi	the population standardized ANCOVA contrast
estimated.psi	the estimated standardized ANCOVA contrast
c.weights	the contrast weights
desired.width	the desired full width of the obtained confidence interval
selected.n	selected sample size to use in order to determine distributional properties of at a given value of sample size
mu.x	the population mean for the covariate
sigma.x	the population standard deviation of the covariate
rho	the population correlation coefficient between the response and the covariate
divisor	which error standard deviation to be used in standardizing the contrast; the value can be either "s.ancova" or "s.anova"

assurance	parameter to ensure that the obtained confidence interval width is narrower than the desired width with a specified degree of certainty (must be NULL or between zero and unity)
conf.level	the desired confidence interval coverage, (i.e., 1 - Type I error rate)
G	number of generations (i.e., replications) of the simulation
print.iter	to print the current value of the iterations
detail	whether the user needs a detailed (TRUE) or brief (FALSE) report of the simulation results; the detailed report includes all the raw data in the simulations
...	allows one to potentially include parameter values for inner functions

Details

The sample size planning method this function is based on is developed in the context of simple (i.e., one-response-one-covariate) ANCOVA model and randomized design (i.e., same population covariate mean across groups).

An ANCOVA contrast can be standardized in at least two ways: (a) divided by the error standard deviation of the ANOVA model, (b) divided by the error standard deviation of the ANCOVA model. This function can be used to analyze both types of standardized ANCOVA contrasts.

The population mean and standard deviation of the covariate does not affect the sample size planning procedure; they can be specified as any values that are considered as reasonable by the user.

Value

psi.obs	observed standardized contrast in each iteration
Full.Width	vector of the full confidence interval width
Width.from.psi.obs.Lower	vector of the lower confidence interval width
Width.from.psi.obs.Upper	vector of the upper confidence interval width
Type.I.Error.Upper	iterations where a Type I error occurred on the upper end of the confidence interval
Type.I.Error.Lower	iterations where a Type I error occurred on the lower end of the confidence interval
Type.I.Error	iterations where a Type I error happens
Lower.Limit	the lower limit of the obtained confidence interval
Upper.Limit	the upper limit of the obtained confidence interval
replications	number of replications of the simulation
True.psi	population standardized contrast
Estimated.psi	estimated standardized contrast
Desired.Width	the desired full width of the obtained confidence interval

assurance the value assigned to the argument assurance
 Sample.Size.per.Group
 sample size per group
 Number.of.Groups
 number of groups
 mean.full.width
 mean width of the obtained full confidence intervals
 median.full.width
 median width of the obtained full confidence intervals
 sd.full.width
 standard deviation of the widths of the obtained full confidence intervals
 Pct.Width.obs.NARROWER.than.desired
 percentage of the obtained full confidence interval widths that are narrower than
 the desired width
 mean.Width.from.psi.obs.Lower
 mean lower width of the obtained confidence intervals
 mean.Width.from.psi.obs.Upper
 mean upper width of the obtained confidence intervals
 Type.I.Error.Upper
 Type I error rate from the upper side
 Type.I.Error.Lower
 Type I error rate from the lower side
 Type.I.Error Type I error rate

Sensitivity analysis for sample size planning for the standardized ANOVA contrast from the Accuracy in Parameter Estimation (AIPE) Perspective

Description

Performs a sensitivity analysis when planning sample size from the Accuracy in Parameter Estimation (AIPE) Perspective for the standardized ANOVA contrast.

Usage

```
ss.aipe.sc.sensitivity(true.psi = NULL, estimated.psi = NULL, c.weights,
desired.width = NULL, selected.n = NULL, assurance = NULL, certainty=NULL,
conf.level = 0.95, G = 10000, print.iter = TRUE, detail = TRUE, ...)
```

Arguments

<code>true.psi</code>	population standardized contrast
<code>estimated.psi</code>	estimated standardized contrast
<code>c.weights</code>	the contrast weights
<code>desired.width</code>	the desired full width of the obtained confidence interval
<code>selected.n</code>	selected sample size to use in order to determine distributional properties of at a given value of sample size
<code>assurance</code>	parameter to ensure that the obtained confidence interval width is narrower than the desired width with a specified degree of certainty (must be NULL or between zero and unity)
<code>certainty</code>	an alias for <code>assurance</code>
<code>conf.level</code>	the desired confidence interval coverage, (i.e., 1 - Type I error rate)
<code>G</code>	number of generations (i.e., replications) of the simulation
<code>print.iter</code>	to print the current value of the iterations
<code>detail</code>	whether the user needs a detailed (TRUE) or brief (FALSE) report of the simulation results; the detailed report includes all the raw data in the simulations
<code>...</code>	allows one to potentially include parameter values for inner functions

Value

<code>psi.obs</code>	observed standardized contrast in each iteration
<code>Full.Width</code>	vector of the full confidence interval width
<code>Width.from.psi.obs.Lower</code>	vector of the lower confidence interval width

Width.from.psi.obs.Upper
 vector of the upper confidence interval width
 Type.I.Error.Upper
 iterations where a Type I error occurred on the upper end of the confidence interval
 Type.I.Error.Lower
 iterations where a Type I error occurred on the lower end of the confidence interval
 Type.I.Error
 iterations where a Type I error happens
 Lower.Limit
 the lower limit of the obtained confidence interval
 Upper.Limit
 the upper limit of the obtained confidence interval
 replications
 number of replications of the simulation
 True.psi
 population standardized contrast
 Estimated.psi
 estimated standardized contrast
 Desired.Width
 the desired full width of the obtained confidence interval
 assurance
 the value assigned to the argument assurance
 Sample.Size.per.Group
 sample size per group
 Number.of.Groups
 number of groups
 mean.full.width
 mean width of the obtained full confidence intervals
 median.full.width
 median width of the obtained full confidence intervals
 sd.full.width
 standard deviation of the widths of the obtained full confidence intervals
 Pct.Width.obs.NARROWER.than.desired
 percentage of the obtained full confidence interval widths that are narrower than the desired width
 mean.Width.from.psi.obs.Lower
 mean lower width of the obtained confidence intervals
 mean.Width.from.psi.obs.Upper
 mean upper width of the obtained confidence intervals
 Type.I.Error.Upper
 Type I error rate from the upper side
 Type.I.Error.Lower
 Type I error rate from the lower side

ss.aipe.sem.path *Sample size planning for SEM targeted effects*

Description

Plan sample size for structural equation models so that the confidence intervals for the model parameters of interest are sufficiently narrow

Usage

```
ss.aipe.sem.path(model, Sigma, desired.width, which.path,
conf.level = 0.95, assurance = NULL, ...)
```

Arguments

model	an RAM (reticular action model; e.g., McArdle & McDonald, 1984) specification of a structural equation model, and should be of class <code>mod</code> . The model is specified in the same manner as does the <code>sem</code> package; see <code>sem</code> and <code>specify.model</code> for detailed documentation about model specifications in the RAM notation.
Sigma	estimated population covariance matrix of the manifest variables
desired.width	desired confidence interval width for the model parameter of interest
which.path	the name of the model parameter of interest, presented in double quotation marks

<code>conf.level</code>	confidence level (i.e., 1- Type I error rate)
<code>assurance</code>	the assurance that the confidence interval obtained in a particular study will be no wider than desired (must be <code>NULL</code> or a value between 0.50 and 1)
<code>...</code>	allows one to potentially include parameter values for inner functions

Details

This function implements the sample size planning methods proposed in Lai and Kelley (2010). It depends on the function `sem` in the `sem` package to calculate the expected information matrix, and uses the same notation to specify SEM models as does `sem`. Please refer to `sem` for more detailed documentations about model specification, the RAM notation, and model fitting techniques. For technical discussion on how to obtain the model implied covariance matrix in the RAM notation given model parameters, see McArdle and McDonald (1984).

Value

<code>parameters</code>	the names of the model parameters
<code>path.index</code>	the index of the model parameter of interest
<code>sample.size</code>	the necessary sample size calculated
<code>obs.vars</code>	the names of the observed variables
<code>var.theta.j</code>	the population variance of the model parameter of interest at the calculated sample size

eta2 -> y9, lambda9, 1
x11 -> eta1, gamma11, 0.6
eta1 -> eta2, beta21, 0.6
x11 <-> x11, phi11, 0.49
eta1 <-> eta1, psi11, 0.3136
eta2 <-> eta2, psi22, 0.3136
y1 <-> y1, delta1, 0.51
y2 <-> y2, delta2, 0.51
y3 <-> y3, delta3, 0.51
y4 <-> y4, delta4, 0.2895
y5 <-> y5, delta5, 0.51
y6 <-> y6, delta6, 0.2895
y7 <-> y7, delta7, 0.2895
y8 <-> y8, delta8, 0.51
y9 <-> y9, delta9, 0.51

# to inspect the specified model
model.2

# one way to specify the population covariance matrix is to first
# specify path coefficients and then calculate the model-implied
# covariance matrix
theta <- c(1, 1, 0.3, 1,1, 0.3, 0.3, 1, 1, 0.6, 0.6,
0.49, 0.3136, 0.3136, 0.51, 0.51, 0.51, 0.2895, 0.51, 0.2895, 0.2895, 0.51, 0.51)

names(theta) <- c("lambda1","lambda2","lambda3",
"lambda4","lambda5","lambda6","lambda7","lambda8","lambda9",
"gamma11", "beta21",
"phi11", "psi11", "psi22",
"delta1","delta2","delta3","delta4","delta5","delta6","delta7",
"delta8","delta9")

res<-theta.2.Sigma.theta(model=model.2, theta=theta,
latent.vars=c("x11", "eta1","eta2"))

Sigma.theta <- res$Sigma.theta
# thus 'Sigma.theta' is the input covariance matrix for sample size

```

```
# planning procedure.

# the necessary sample size can be calculated as follows.
# ss.aipe.sem.path(model=model.2, Sigma=Sigma.theta,
# desired.width=0.3, which.path="beta21")

## End(Not run)
```

```
ss.aipe.sem.path.sensitiv
    a priori Monte Carlo simulation for sample size planning for SEM
    targeted effects
```

Description

Conduct a priori Monte Carlo simulation to empirically study the effects of (mis)specifications of input information on the calculated sample size. Random data are generated from the true covariance matrix but fit to the proposed model, whereas sample size is calculated based on the input covariance matrix and proposed model.

Usage

```
ss.aipe.sem.path.sensitiv(model, est.Sigma, true.Sigma = est.Sigma,
  which.path, desired.width, N=NULL, conf.level = 0.95, assurance = NULL,
  G = 100, ...)
```

Arguments

model	the model the researcher proposes, may or may not be the true model. This argument should be an RAM (reticular action model; e.g., McArdle & McDonald, 1984) specification of a structural equation model, and should be of class <code>mod</code> . The model is specified in the same manner as does the <code>sem</code> package; see <code>sem</code> and <code>specify.model</code> for detailed documentation about model specifications in the RAM notation.
est.Sigma	the covariance matrix used to calculate sample size, may or may not be the true covariance matrix. The row names and column names of <code>est.Sigma</code> should be the same as the manifest variables in <code>est.model</code> .
true.Sigma	the true population covariance matrix, which will be used to generate random data for the simulation study. The row names and column names of <code>est.Sigma</code> should be the same as the manifest variables in <code>est.model</code> .
which.path	the name of the model parameter of interest, and must be in a double quote
desired.width	desired confidence interval width for the model parameter of interest
N	the sample size of random data. If it is <code>NULL</code> , it will be determined by the sample size planning method
conf.level	confidence level (i.e., 1- Type I error rate)

assurance	the assurance that the confidence interval obtained in a particular study will be no wider than desired (must be NULL or a value between 0.50 and 1)
G	number of replications in the Monte Carlo simulation
...	allows one to potentially include parameter values for inner functions

Details

This function implements the sample size planning methods proposed in Lai and Kelley (2010). It depends on the function `sem` in the `sem` package to calculate the expected information matrix, and uses the same notation to specify SEM models as does `sem`. Please refer to `sem` for more detailed documentation about model specifications, the RAM notation, and model fitting techniques. For technical discussion on how to obtain the model implied covariance matrix in the RAM notation given model parameters, see McArdle and McDonald (1984).

Value

<code>w</code>	the G random confidence interval widths
<code>sample.size</code>	the sample size calculated
<code>path.of.interest</code>	name of the model parameter of interest
<code>desired.width</code>	desired confidence interval width
<code>mean.width</code>	mean of the G random confidence interval widths
<code>median.width</code>	median of the G random confidence interval widths
<code>quantile.width</code>	99, 95, 90, 85, 80, 75, 70, and 60 percentiles of the G random confidence interval widths
<code>width.less.than.desired</code>	the proportion of confidence interval widths narrower than desired
<code>Type.I.err.upper</code>	the upper empirical Type I error rate
<code>Type.I.err.lower</code>	the lower empirical Type I error rate
<code>Type.I.err</code>	total empirical Type I error rate
<code>conf.level</code>	confidence level
<code>rep</code>	successful replications

Note

Sometimes the simulation stops in the middle of fitting the model to the random data. The reason is because `nlm`, the function `sem` calls to fit the model, fails to converge. We suggest using the `try` function in simulation so that the simulation can proceed with unsuccessful iterations.

ss.aipe.sm

*Sample size planning for Accuracy in Parameter Estimation (AIPE) of
the standardized mean*

Description

A function to calculate the appropriate sample size for the standardized mean such that the width of the confidence interval is sufficiently narrow.

Usage

```
ss.aipe.sm(sm, width, conf.level = 0.95, assurance = NULL, certainty=NULL, ...)
```

Arguments

<code>sm</code>	the population standardized mean
<code>width</code>	the desired full width of the obtained confidence interval
<code>conf.level</code>	the desired confidence interval coverage, (i.e., 1 - Type I error rate)
<code>assurance</code>	parameter to ensure that the obtained confidence interval width is narrower than the desired width with a specified degree of certainty (must be NULL or between zero and unity)
<code>certainty</code>	an alias for <code>assurance</code>
<code>...</code>	allows one to potentially include parameter values for inner functions

Value

<code>n</code>	the necessary sample size in order to achieve the desired degree of accuracy (i.e., the sufficiently narrow confidence interval)

Examples

```
# Suppose the population mean is believed to be 20, and the population
# standard deviation is believed to be 2; thus the population standardized
# mean is believed to be 10. To determine the necessary sample size for a
# study so that the full width of the 95 percent confidence interval
# obtained in the study will be, with 90% assurance, no wider than 2.5,
# the function should be specified as follows.

# ss.aipe.sm(sm=10, width=2.5, conf.level=.95, assurance=.90)
```

```
ss.aipe.sm.sensitivity
    Sensitivity analysis for sample size planning for the standardized mean
    from the Accuracy in Parameter Estimation (AIPE) Perspective
```

Description

Performs a sensitivity analysis when planning sample size from the Accuracy in Parameter Estimation (AIPE) Perspective for the standardized mean.

Usage

```
ss.aipe.sm.sensitivity(true.sm = NULL, estimated.sm = NULL,
desired.width = NULL, selected.n = NULL, assurance = NULL,
certainty=NULL, conf.level = 0.95, G = 10000, print.iter = TRUE,
detail = TRUE, ...)
```

Arguments

<code>true.sm</code>	population standardized mean
<code>estimated.sm</code>	estimated standardized mean
<code>desired.width</code>	desired full width of the confidence interval for the population standardized mean
<code>selected.n</code>	selected sample size to use in order to determine distributional properties of at a given value of sample size
<code>assurance</code>	parameter to ensure that the obtained confidence interval width is narrower than the desired width with a specified degree of certainty (must be NULL or between zero and unity)
<code>certainty</code>	an alias for <code>assurance</code>
<code>conf.level</code>	the desired confidence interval coverage, (i.e., 1 - Type I error rate)
<code>G</code>	number of generations (i.e., replications) of the simulation
<code>print.iter</code>	to print the current value of the iterations
<code>detail</code>	whether the user needs a detailed (TRUE) or brief (FALSE) report of the simulation results; the detailed report includes all the raw data in the simulations
<code>...</code>	allows one to potentially include parameter values for inner functions

Value

sm.obs	vector of the observed standardized mean
Full.Width	vector of the full confidence interval width
Width.from.sm.obs.Lower	vector of the lower confidence interval width
Width.from.sm.obs.Upper	vector of the upper confidence interval width
Type.I.Error.Upper	iterations where a Type I error occurred on the upper end of the confidence interval
Type.I.Error.Lower	iterations where a Type I error occurred on the lower end of the confidence interval
Type.I.Error	iterations where a Type I error happens
Lower.Limit	the lower limit of the obtained confidence interval
Upper.Limit	the upper limit of the obtained confidence interval
replications	number of replications of the simulation
True.sm	the population standardized mean
Estimated.sm	the estimated standardized mean
Desired.Width	the desired full confidence interval width
assurance	parameter to ensure that the obtained confidence interval width is narrower than the desired width with a specified degree of certainty
Sample.Size	the sample size used in the simulation
mean.full.width	mean width of the obtained full confidence intervals
median.full.width	median width of the obtained full confidence intervals
sd.full.width	standard deviation of the widths of the obtained full confidence intervals
Pct.Width.obs.NARROWER.than.desired	percentage of the obtained full confidence interval widths that are narrower than the desired width
mean.Width.from.sm.obs.Lower	mean lower width of the obtained confidence intervals
mean.Width.from.sm.obs.Upper	mean upper width of the obtained confidence intervals
Type.I.Error.Upper	Type I error rate from the upper side
Type.I.Error.Lower	Type I error rate from the lower side

# Res.2$Summary$mean.full.width
```

ss.aipe.smd	<i>Sample size planning for the standardized mean difference from the Accuracy in Parameter Estimation (AIPE) perspective</i>
-------------	---

Description

A function to calculate the appropriate sample size for the standardized mean difference such that the expected value of the confidence interval is sufficiently narrow, optionally with a `degree.of.certainty`.

Usage

```
ss.aipe.smd(delta, conf.level, width, which.width="Full",
degree.of.certainty=NULL, assurance=NULL, certainty=NULL, ...)
```

Arguments

<code>delta</code>	the population value of the standardized mean difference
<code>conf.level</code>	the desired degree of confidence (i.e., 1-Type I error rate)
<code>width</code>	desired width of the specified (i.e., <code>Full</code> , <code>Lower</code> , and <code>Upper</code> widths) region of the confidence interval
<code>which.width</code>	the width that the <code>width</code> argument refers identifies the width of interest (i.e., <code>Full</code> , <code>Lower</code> , and <code>Upper</code> widths)
<code>degree.of.certainty</code>	parameter to ensure confidence interval width with a specified degree of certainty
<code>assurance</code>	an alias for <code>degree.of.certainty</code>
<code>certainty</code>	an alias for <code>degree.of.certainty</code>
<code>...</code>	for modifying parameters of functions this function calls upon

Value

Returns the necessary sample size **per group** in order to achieve the desired degree of accuracy (i.e., the sufficiently narrow confidence interval).

Warning

Finding sample size for lower and upper confidence limits is approximate, but very close to being exact. The `pt()` function is limited to accurate values when the noncentral parameter is less than 37.62.

Note

The function `ss.aipe.smd` is the preferred function, and is the one that is recommended for widespread use. The functions `ss.aipe.smd.lower`, `ss.aipe.smd.upper` and `ss.aipe.smd.full` are called from the `ss.aipe.smd` function.

```

```
ss.aipe.smd.sensitivity
```

Sensitivity analysis for sample size given the Accuracy in Parameter Estimation approach for the standardized mean difference.

Description

Performs sensitivity analysis for sample size determination for the standardized mean difference given a population and an standardized mean difference. Allows one to determine the effect of being wrong when estimating the population standardized mean difference in terms of the width of the obtained (two-sided) confidence intervals.

Usage

```
ss.aipe.smd.sensitivity(true.delta = NULL, estimated.delta = NULL,
desired.width = NULL, selected.n=NULL, assurance=NULL, certainty = NULL,
conf.level = 0.95, G = 10000, print.iter = TRUE, ...)
```

Arguments

<code>true.delta</code>	population standardized mean difference
<code>estimated.delta</code>	estimated standardized mean difference; can be <code>true.delta</code> to perform standard simulations
<code>desired.width</code>	describe full width for the confidence interval around the population standardized mean difference
<code>selected.n</code>	selected sample size to use in order to determine distributional properties of at a given value of sample size
<code>assurance</code>	parameter to ensure confidence interval width with a specified degree of certainty (must be <code>NULL</code> or between zero and unity)
<code>certainty</code>	an alias for <code>assurance</code>
<code>conf.level</code>	the desired degree of confidence (i.e., 1-Type I error rate).
<code>G</code>	number of generations (i.e., replications) of the simulation
<code>print.iter</code>	to print the current value of the iterations
<code>...</code>	for modifying parameters of functions this function calls

Details

For sensitivity analysis when planning sample size given the desire to obtain narrow confidence intervals for the population standardized mean difference. Given a population value and an estimated value, one can determine the effects of incorrectly specifying the population standardized mean difference (`true.delta`) on the obtained widths of the confidence intervals. Also, one can evaluate the percent of the confidence intervals that are less than the desired width (especially when modifying the `certainty` parameter); see `ss.aipe.smd`

Alternatively, one can specify `selected.n` to determine the results at a particular sample size (when doing this `estimated.delta` cannot be specified).

Value

<code>Results</code>	list of the results in <code>G</code> -length vector form
<code>Specifications</code>	specification of the function
<code>Summary</code>	summary measures of some important descriptive statistics
<code>d</code>	contained in <code>Results</code> list: vector of the observed <code>d</code> values
<code>Full.Width</code>	contained in <code>Results</code> list: vector of

Width.from.d.Upper	contained in Results list: vector of the observed upper widths of the confidence interval (upper limit minus observed standardized mean difference)
Width.from.d.Lower	contained in Results list: vector of the observed lower widths of the confidence interval (standardized mean difference minus lower limit)
Type.I.Error.Upper	contained in Results list: iterations where a Type I error occurred on the upper end of the confidence interval
Type.I.Error.Lower	contained in Results list: iterations where a Type I error occurred on the lower end of the confidence interval
Type.I.Error	contained in Results list: iterations where a Type I error occurred
Upper.Limit	contained in Results list: vector of the obtained upper limits from the simulation
Low.Limit	contained in Results list: vector of the obtained lower limits from the simulation
replications	contained in Specifications list: number of generations (i.e., replication) of the simulation
true.delta	contained in Specifications list: population value of the standardized mean difference
estimated.delta	contained in Specifications list: value of the population (mis)specified for purposes of sample size planning
desired.width	contained in Specifications list: desired full width of the confidence interval around the population standardized mean difference
certainty	contained in Specifications list: desired degree of certainty that the obtained confidence interval width is less than the value specified
n.j	contained in Specifications list: sample size per group given the specifications
mean.full.width	contained in Summary list: mean width of the obtained confidence intervals
median.full.width	contained in Summary list: median width of the obtained confidence intervals
sd.full.width	contained in Summary list: standard deviation of the obtained confidence intervals
Pct.Less.Desired	contained in Summary list: Percent of the confidence widths less than the width specified.
mean.Width.from.d.Lower	contained in Summary list: mean width of the lower portion of the confidence interval (from d)

```

mean.Width.from.d.Upper
    contained in Summary list: mean width of the upper portion of the confidence
    interval (from d)
Type.I.Error.Upper
    contained in Summary list: Type I error rate from upper side
Type.I.Error.Lower
    contained in Summary list: Type I error rate from the lower side

```

Note

Returns three lists, where each list has multiple components.

ss.aipe.src	<i>sample size necessary for the accuracy in parameter estimation approach for a standardized regression coefficient of interest</i>
-------------	--

Description

A function used to plan sample size from the accuracy in parameter estimation approach for a standardized regression coefficient of interest given the input specification.

Usage

```

ss.aipe.src(Rho2.Y_X = NULL, Rho2.k_X.without.k = NULL, K = NULL,
beta.k = NULL, width, which.width = "Full", sigma.Y = 1, sigma.X.k = 1,
RHO.XX = NULL, Rho.YX = NULL, which.predictor = NULL,
alpha.lower = NULL, alpha.upper = NULL, conf.level = .95,
degree.of.certainty = NULL, assurance=NULL, certainty=NULL,
Suppress.Statement = FALSE)

```

Arguments

Rho2.Y_X	Population value of the squared multiple correlation coefficient
Rho2.k_X.without.k	Population value of the squared multiple correlation coefficient predicting the k th predictor variable from the remaining $p-1$ predictor variables
K	the number of predictor variables

<code>beta.k</code>	the regression coefficient for the k th predictor variable (i.e., the predictor of interest)
<code>width</code>	the desired width of the confidence interval
<code>which.width</code>	which width ("Full", "Lower", or "Upper") the width refers to (at present, only "Full" can be specified)
<code>sigma.Y</code>	the population standard deviation of Y (i.e., the dependent variables)
<code>sigma.X.k</code>	the population standard deviation of the k th X variable (i.e., the predictor variable of interest)
<code>RHO.XX</code>	Population correlation matrix for the p predictor variables
<code>Rho.YX</code>	Population p length vector of correlation between the dependent variable (Y) and the p independent variables
<code>which.predictor</code>	identifies which of the p predictors is of interest
<code>alpha.lower</code>	Type I error rate for the lower confidence interval limit
<code>alpha.upper</code>	Type I error rate for the upper confidence interval limit
<code>conf.level</code>	desired level of confidence for the computed interval (i.e., 1 - the Type I error rate)
<code>degree.of.certainty</code>	degree of certainty that the obtained confidence interval will be sufficiently narrow, which yields an approximate sample size to be verified with function <code>ss.aipe.reg.coef.sensitivity</code> to determine if it is appropriate.
<code>assurance</code>	an alias for <code>degree.of.certainty</code>
<code>certainty</code>	an alias for <code>degree.of.certainty</code>
<code>Suppress.Statement</code>	TRUE/FALSE statement whether or not a sentence describing the situation defined is printed with the necessary sample size

Details

Not all of the arguments need to be specified, only those that provide all of the necessary information so that the sample size can be determined for the conditions specified.

Value

Returns the necessary sample size in order for the goals of accuracy in parameter estimation to be satisfied for the confidence interval for a particular regression coefficient given the input specifications.

Warning

As discussed in Kelley and Maxwell (2008), the sample size planning approach from the AIPE perspective used in this function is only an approximation.

Note

This function calls upon `ss.aipe.reg.coef` in MBESS but has a different naming scheme. See `ss.aipe.reg.coef` for more details.

Examples

```
# Exchangable correlation structure
# Rho.YX <- c(.3, .3, .3, .3, .3)
# RHO.XX <- rbind(c(1, .5, .5, .5, .5), c(.5, 1, .5, .5, .5), c(.5, .5, 1, .5, .5),
# c(.5, .5, .5, 1, .5), c(.5, .5, .5, .5, 1))

# ss.aipe.src(width=.1, which.width="Full", sigma.Y=1, sigma.X=1, RHO.XX=RHO.XX,
# Rho.YX=Rho.YX, which.predictor=1, conf.level=1-.05)

# ss.aipe.src(width=.1, which.width="Full", sigma.Y=1, sigma.X=1, RHO.XX=RHO.XX,
# Rho.YX=Rho.YX, which.predictor=1, conf.level=1-.05, degree.of.certainty=.85)
```

```
ss.aipe.src.sensitivity
```

Sensitivity analysis for sample size planing from the Accuracy in Parameter Estimation Perspective for the standardized regression coefficient

Description

Performs a sensitivity analysis when planning sample size from the Accuracy in Parameter Estimation Perspective for the standardized regression coefficient.

Usage

```
ss.aipe.src.sensitivity(True.Var.Y = NULL, True.Cov.YX = NULL,
True.Cov.XX = NULL, Estimated.Var.Y = NULL, Estimated.Cov.YX = NULL,
Estimated.Cov.XX = NULL, Specified.N = NULL, which.predictor = 1,
w = NULL, Noncentral = TRUE, Standardize = TRUE, conf.level = 0.95,
degree.of.certainty = NULL, assurance=NULL, certainty=NULL,
G = 1000, print.iter = TRUE)
```

Arguments

<code>True.Var.Y</code>	Population variance of the dependent variable (Y)
<code>True.Cov.YX</code>	Population covariances vector between the p predictor variables and the dependent variable (Y)
<code>True.Cov.XX</code>	Population covariance matrix of the p predictor variables
<code>Estimated.Var.Y</code>	Estimated variance of the dependent variable (Y)
<code>Estimated.Cov.YX</code>	Estimated covariances vector between the p predictor variables and the dependent variable (Y)
<code>Estimated.Cov.XX</code>	Estimated Population covariance matrix of the p predictor variables
<code>Specified.N</code>	Directly specified sample size (instead of using <code>Estimated.Rho.YX</code> and <code>Estimated.RHO.XX</code>)
<code>which.predictor</code>	identifies which of the p predictors is of interest
<code>w</code>	desired confidence interval width for the regression coefficient of interest
<code>Noncentral</code>	specify with a TRUE/FALSE statement whether or not the noncentral approach to sample size planning should be used
<code>Standardize</code>	specify with a TRUE/FALSE statement whether or not the regression coefficient will be standardized; default is TRUE
<code>conf.level</code>	desired level of confidence for the computed interval (i.e., 1 - the Type I error rate)
<code>degree.of.certainty</code>	degree of certainty that the obtained confidence interval will be sufficiently narrow
<code>assurance</code>	an alias for <code>degree.of.certainty</code>
<code>certainty</code>	an alias for <code>degree.of.certainty</code>
<code>G</code>	the number of generations/replication of the simulation study within the function
<code>print.iter</code>	specify with a TRUE/FALSE statement if the iteration number should be printed as the simulation within the function runs

Details

Direct specification of `True.Rho.YX` and `True.RHO.XX` is necessary, even if one is interested in a single regression coefficient, so that the covariance/correlation structure can be specified when the simulation study within the function runs.

Value

<code>Results</code>	a matrix containing the empirical results from each of the G replication of the simulation
<code>Specifications</code>	a list of the input specifications and the required sample size

Summary.of.Results

summary values for the results of the sensitivity analysis (simulation study) given the input specification

Note

Note that when True.Rho.YX=Estimated.Rho.YX and True.RHO.XX=Estimated.RHO.XX, the results are not literally from a sensitivity analysis, rather the function performs a standard simulation study. A simulation study can be helpful in order to determine if the sample size procedure under or overestimates necessary sample size.

See `ss.aipe.reg.coef.sensitivity` in MBESS for more details.

ss.power.pcm

Sample size planning for power for polynomial change models

Description

Returns power given the sample size, or sample size given the desired power, for polynomial change models

Usage

`ss.power.pcm(beta, tau, level.1.variance, frequency, duration, desired.power = NULL)`

Arguments

<code>beta</code>	the level two regression coefficient for the group by time interaction; where "X" is coded -.5 and .5 for the two groups.
<code>tau</code>	the true variance of the individuals' slopes
<code>level.1.variance</code>	level one variance
<code>frequency</code>	frequency of measurements per unit of time duration of the study in the particular units (e.g., age, hours, grade level, years, etc.)

duration time in some number of units (e.g., years)
 desired.power desired power
 N sample size
 alpha.level Type I error rate
 standardized the standardized slope is the unstandardized slope divided by the square root of tau, the variance of the unique effects for beta.
 directional should a one (TRUE) or two (FALSE) tailed test be performed.

```

ss.power.R2 *Function to plan sample size so that the test of the squared multiple correlation coefficient is sufficiently powerful.*

Description

Function for determining the necessary sample size for the test of the squared multiple correlation coefficient or for determining the statistical power given a specified sample size for the squared multiple correlation coefficient in models where the regressors are regarded as fixed.

Usage

```
ss.power.R2(Population.R2 = NULL, alpha.level = 0.05, desired.power = 0.85,
p, Specified.N = NULL, Cohen.f2 = NULL, Null.R2 = 0,
Print.Progress = FALSE, ...)
```

Arguments

Population.R2	Population squared multiple correlation coefficient
alpha.level	Type I error rate
desired.power	desired degree of statistical power
p	the number of predictor variables
Specified.N	the sample size used to calculate power (rather than determine necessary sample size)
Cohen.f2	Cohen's (1988) effect size for multiple regression: $\text{Population.R2} / (1 - \text{Population.R2})$
Null.R2	value of the null hypothesis that the squared multiple correlation will be evaluated against (this will typically be zero)
Print.Progress	if the progress of the iterative procedure is printed to the screen as the iterations are occurring
...	(not currently implemented) possible additional parameters for internal functions

Details

Determine the necessary sample size given a particular `Population.R2`, `alpha.level`, `p`, and `desired.power`. Alternatively, given `Population.R2`, `alpha.level`, `p`, and `Specified.N`, the function can be used to determine the statistical power.

Value

Sample.Size	returns either <code>Necessary.Sample.Size</code> or <code>Specified.Sample.Size</code> , depending on if sample size is being determined for a desired degree of statistical power analysis or if statistical power is being determined given a specified sample size, respectively
Actual.Power	Actual power of the situation described

Note

When determining sample size for a desired degree of power, there will always be a slightly larger degree of actual power. This is the case because the algorithm employed determines sample size until the actual power is no less than the desired power (given sample size is a whole number power will almost certainly not be exactly the specified value). This is the same as other statistical power procedures that return whole numbers for necessary sample size.

```

ss.power.rc

sample size for a targeted regression coefficient

Description

Determine the necessary sample size for a targeted regression coefficient or determine the degree of power given a specified sample size

Usage

```
ss.power.rc(Rho2.Y_X = NULL, Rho2.Y_X.without.k = NULL, K = NULL,
desired.power = 0.85, alpha.level = 0.05, Directional = FALSE,
beta.k = NULL, sigma.X = NULL, sigma.Y = NULL,
Rho2.k_X.without.k = NULL, RHO.XX = NULL, Rho.YX = NULL,
which.predictor = NULL, Cohen.f2 = NULL, Specified.N = NULL,
Print.Progress = FALSE)
```

Arguments

Rho2.Y_X	population squared multiple correlation coefficient predicting the dependent variable (i.e., Y) from the p predictor variables (i.e., the X variables)
Rho2.Y_X.without.k	population squared multiple correlation coefficient predicting the dependent variable (i.e., Y) from the K-1 predictor variables, where the one not used is the predictor of interest
K	number of predictor variables
desired.power	desired degree of statistical power for the test of targeted regression coefficient
alpha.level	Type I error rate
Directional	whether or not a direction or a nondirectional test is to be used (usually <code>directional=FALSE</code>)
beta.k	population value of the regression coefficient for the predictor of interest
sigma.X	population standard deviation for the predictor variable of interest
sigma.Y	population standard deviation for the outcome variable

Rho2.k_X.without.k	population squared multiple correlation coefficient predicting the predictor variable of interest from the remaining K-1 predictor variables
RHO.XX	population correlation matrix for the p predictor variables
Rho.YX	population vector of correlation coefficient between the p predictor variables and the criterion variable
which.predictor	identifies the predictor of interest when RHO.XX and Rho.YX are specified
Cohen.f2	Cohen's (1988) definition for an effect size for a targeted regression coefficient: $(Rho2.Y_X - Rho2.Y_X.without.j)/(1 - Rho2.Y_X)$
Specified.N	sample size for which power should be evaluated
Print.Progress	if the progress of the iterative procedure is printed to the screen as the iterations are occurring

Details

Determine the necessary sample size given a desired level of statistical power. Alternatively, determines the statistical power for a given a specified sample size. There are a number of ways that the specification regarding the size of the regression coefficient can be entered. The most basic, and often the simplest, is to specify Rho2.Y_X and Rho2.Y_X.without.k. See the examples section for several options.

Value

Sample.Size	either the necessary sample size or the specified sample size, depending if one is interested in determining the necessary sample size given a desired degree of statistical power or if one is interested in the determining the value of statistical power given a specified sample size, respectively
Actual.Power	Actual power of the situation described
Noncentral.t.Parm	value of the noncentral distribution for the appropriate t-distribution
Effect.Size.NC.t	effect size for the noncentral t-distribution; this is the square root of Cohen.f2, because Cohen.f2 is the effect size using an F-distribution

```

ss.power.reg.coef *sample size for a targeted regression coefficient*

Description

Determine the necessary sample size for a targeted regression coefficient or determine the degree of power given a specified sample size

Usage

```

ss.power.reg.coef(Rho2.Y_X = NULL, Rho2.Y_X.without.j = NULL, p = NULL,
desired.power = 0.85, alpha.level = 0.05, Directional = FALSE,
beta.j = NULL, sigma.X = NULL, sigma.Y = NULL, Rho2.j_X.without.j = NULL,
RHO.XX = NULL, Rho.YX = NULL, which.predictor = NULL, Cohen.f2 = NULL,
Specified.N=NULL, Print.Progress = FALSE)

```

Arguments

Rho2.Y_X	population squared multiple correlation coefficient predicting the dependent variable (i.e., Y) from the p predictor variables (i.e., the X variables)
Rho2.Y_X.without.j	population squared multiple correlation coefficient predicting the dependent variable (i.e., Y) from the p-1 predictor variables, where the one not used is the predictor of interest
p	number of predictor variables
desired.power	desired degree of statistical power for the test of targeted regression coefficient
alpha.level	Type I error rate

<code>Directional</code>	whether or not a direction or a nondirectional test is to be used (usually <code>directional=FALSE</code>)
<code>beta.j</code>	population value of the regression coefficient for the predictor of interest
<code>sigma.X</code>	population standard deviation for the predictor variable of interest
<code>sigma.Y</code>	population standard deviation for the outcome variable
<code>Rho2.j_X.without.j</code>	population squared multiple correlation coefficient predicting the predictor variable of interest from the remaining $p-1$ predictor variables
<code>RHO.XX</code>	population correlation matrix for the p predictor variables
<code>Rho.YX</code>	population vector of correlation coefficient between the p predictor variables and the criterion variable
<code>Cohen.f2</code>	Cohen's (1988) definition for an effect size for a targeted regression coefficient: $(\text{Rho2.Y_X} - \text{Rho2.Y_X.without.j}) / (1 - \text{Rho2.Y_X})$
<code>which.predictor</code>	identifies the predictor of interest when <code>RHO.XX</code> and <code>Rho.YX</code> are specified
<code>Specified.N</code>	sample size for which power should be evaluated
<code>Print.Progress</code>	if the progress of the iterative procedure is printed to the screen as the iterations are occurring

Details

Determine the necessary sample size given a desired level of statistical power. Alternatively, determines the statistical power for a given a specified sample size. There are a number of ways that the specification regarding the size of the regression coefficient can be entered. The most basic, and often the simplest, is to specify `Rho2.Y_X` and `Rho2.Y_X.without.j`. See the examples section for several options.

Value

<code>Sample.Size</code>	either the necessary sample size or the specified sample size, depending if one is interested in determining the necessary sample size given a desired degree of statistical power or if one is interested in the determining the value of statistical power given a specified sample size, respectively
<code>Actual.Power</code>	Actual power of the situation described
<code>Noncentral.t.Parm</code>	value of the noncentral distribution for the appropriate t -distribution
<code>Effect.Size.NC.t</code>	effect size for the noncentral t -distribution; this is the square root of <code>Cohen.f2</code> , because <code>Cohen.f2</code> is the effect size using an F -distribution

```

t.and.smd.conversion

Conversion functions for noncentral t-distribution

Description

Functions useful for converting a standardized mean difference to a noncentrality parameter, and vice versa.

Usage

```

lambda2delta(lambda, n.1, n.2)
delta2lambda(delta, n.1, n.2)

```

Arguments

lambda	noncentral value from a t -distribution
delta	population value of the standardized mean difference
n.1	sample size in group 1
n.2	sample size in group 2

Details

Although `lambda` is the population noncentral value, it can be regarded as the observed value of a t -statistics. Likewise, `delta` can be regarded as the observed standardized mean difference. Thus, the observed standardized mean difference can be converted to the observed t -value. These functions are especially helpful in the context of forming confidence intervals around the population standardized mean difference.

Value

Either the value of `delta` given `lambda` or `lambda` given `delta` (and the per-group sample sizes).

Author(s)

Ken Kelley (University of Notre Dame; <KKelley@ND.Edu>)

# delta2lambda(delta=.266076, n.1=113, n.2=113)
```

```
theta.2.Sigma.theta
```

Compute the model-implied covariance matrix of an SEM model

Description

Obtain the model-implied covariance matrix of manifest variables given a structural equation model and its model parameters

Usage

```
theta.2.Sigma.theta(model, theta, latent.vars)
```

Arguments

<code>model</code>	an RAM (reticular action model; e.g., McArdle & McDonald, 1984) specification of a structural equation model, and should be of class <code>mod</code> . The model is specified in the same manner as does the <code>sem</code> package; see <code>sem</code> and <code>specify.model</code> for detailed documentations about model specifications in the RAM notation.
<code>theta</code>	a vector containing the model parameters. The names of the elements in <code>theta</code> must be the same as the names of the model parameters specified in <code>model</code> .
<code>latent.vars</code>	a vector containing the names of the latent variables

Details

Part of the codes in this function are adapted from the function `sem` in the `sem` R package (Fox, 2006). This function uses the same notation to specify SEM models as does `sem`. Please refer to `sem` and the example below for more detailed documentation about model specification and the RAM notation. For technical discussion on how to obtain the model implied covariance matrix in the RAM notation given model parameters, see McArdle and McDonald (1984).

Value

<code>ram</code>	RAM matrix, including any rows generated for covariances among fixed exogenous variables; column 5 includes computed start values.
<code>t</code>	number of model parameters (i.e., the length of <code>theta</code>)
<code>m</code>	total number of variables (i.e., manifest variables plus latent variables)
<code>n</code>	number of observed variables
<code>all.vars</code>	the names of all variables (i.e., manifest plus latent)
<code>obs.vars</code>	the names of observed variables
<code>latent.vars</code>	the names of latent variables
<code>pars</code>	the names of model parameters
<code>P</code>	the P matrix in RAM notation
<code>A</code>	the A matrix in RAM notation
<code>Sigma.theta</code>	the model implied covariance matrix

Variance.R2

Variance of squared multiple correlation coefficient

Description

Function to determine the variance of the squared multiple correlation coefficient given the population squared multiple correlation coefficient, sample size, and the number of predictors.

Usage

```
Variance.R2(Population.R2, N, p)
```

Arguments

Population.R2	population squared multiple correlation coefficient
N	sample size
p	the number of predictor variables

Details

Uses the hypergeometric function as discussed in and section 28 of Stuart, Ord, and Arnold (1999) in order to obtain the *correct* value for the variance of the squared multiple correlation coefficient.

Value

Returns the variance of the of the squared multiple correlation coefficient.

Note

Uses package `gsl` and its `hyperg_2F1` function.

Author(s)

Ken Kelley (University of Notre Dame; <KKelley@ND.Edu>)

```

verify.ss.aipe.R2 *Internal MBESS function for verifying the sample size in ss.aipe.R2*

Description

Internal function called upon by ss.aipe.R2 when verify.ss=TRUE. This function then calls upon ss.aipe.R2.sensitivity for the simulation study.

Usage

```
verify.ss.aipe.R2(Population.R2 = NULL, conf.level = 0.95, width = NULL,
Random.Predictors = TRUE, which.width = "Full", p = NULL, n = NULL,
degree.of.certainty = NULL, g = 500, G = 10000, print.iter=FALSE, ...)
```

Arguments

Population.R2	value of the population multiple correlation coefficient
conf.level	confidence interval level (e.g., .95, .99, .90); 1-Type I error rate
width	width of the confidence interval (see which.width)
Random.Predictors	whether or not the predictor variables are random (set to TRUE) or are fixed (set to FALSE)
which.width	defines the width that width refers to
p	the number of predictor variables
n	starting sample size (i.e., from ss.aipe.R2)
degree.of.certainty	value with which confidence can be placed that describes the likelihood of obtaining a confidence interval less than the value specified (e.g., .80, .90, .95)

<code>g</code>	simulations for the preliminary sample size (much smaller than <code>G</code>)
<code>G</code>	number of replications for the actual Monte Carlo simulation (should be large)
<code>print.iter</code>	specify whether or not the internal iterations should be printed
<code>...</code>	additional arguments passed to internal functions

Details

This function is internal to MBESS and is called upon when `verify.ss=TRUE` in the `ss.aipe.R2` function. Although users can use `verify.ss.aipe.R2` directly, it is not recommended.

Value

Returns the exact (provided `G` is large enough) sample size necessary to satisfy the conditions specified.

Author(s)

Ken Kelley (University of Notre Dame; <KKelley@ND.Edu>)

vit

Visualize individual trajectories

Description

A function to help visualize individual trajectories in a longitudinal (i.e., analysis of change) context.

Usage

```
vit(id = "", occasion = "", score = "", Data = NULL, group = NULL,
    subset.ids = NULL, pct.rand = NULL, number.rand = NULL,
    All.in.One = TRUE, ylab = NULL, xlab = NULL, same.scales = TRUE,
    plot.points = TRUE, save.pdf = FALSE, save.eps = FALSE,
    save.jpg = FALSE, file = "", layout = c(3, 3), col = NULL,
    pch = 16, cex = 0.7, ...)
```

Arguments

<code>id</code>	string variable of the column name of <code>id</code>
<code>occasion</code>	string variable of the column name of time variable
<code>score</code>	string variable of the column name where the score (i.e., dependent variable) is located
<code>Data</code>	data set with named column variables (see above)
<code>group</code>	if plotting parameters should be conditional on group membership
<code>subset.ids</code>	<code>id</code> values for a selected subset of individuals
<code>pct.rand</code>	percentage of random trajectories to be plotted

<code>number.rand</code>	number of random trajectories to be plotted
<code>All.in.One</code>	should trajectories be in a single or multiple plots
<code>ylab</code>	label for the ordinate (i.e., y-axis; see <code>par</code>)
<code>xlab</code>	label for the abscissa (i.e., x-axis; see <code>par</code>)
<code>same.scales</code>	should the y-axes have the same scales
<code>plot.points</code>	should the points be plotted
<code>save.pdf</code>	save a pdf file
<code>save.eps</code>	save a postscript file
<code>save.jpg</code>	save a jpg file
<code>file</code>	file name and file path for the graph(s) to save, if <code>file=""</code> a file would be saved in the current working directory
<code>layout</code>	define the per-page layout when <code>All.in.One==FALSE</code>
<code>col</code>	color(s) of the line(s) and points
<code>pch</code>	plotting character(s); see <code>par</code>
<code>cex</code>	size of the points (1 is the R default; see <code>par</code>)
<code>...</code>	optional plotting specifications

Details

This function makes visualizing individual trajectories simple. Data should be in the "univariate format" (i.e., the same format as `lmer` and `nlme` data.)

Value

Returns a plot of individual trajectories with the specifications provided.

Author(s)

Ken Kelley (University of Notre Dame; <KKelley@ND.Edu>) and Po-Ju Wu (Indiana University; <pojwu@indiana.edu>)

See Also

`par`, `nlme`, `vit.fitted`,

Examples

```
data(Gardner.LD)

# Although many options are possible, a simple call to
# 'vit' is of the form:
# vit(id="ID", occasion= "Trial", score= "Score", Data=Gardner.LD)

# Now color is conditional on group membership.
# vit(id="ID", occasion= "Trial", score="Score", Data=Gardner.LD,
```

```

# group="Group")

# Now randomly selects 50% of the sample to plot
# vit(id="ID", occasion= "Trial", score="Score", Data=Gardner.LD,
# pct.rand=50, group="Group")

# Specified individuals are plotted (by group)
# vit(id="ID", occasion= "Trial", score="Score", Data=Gardner.LD,
# subset.ids=c(1, 4, 8, 13, 17, 21), group="Group")

# Now colors for groups are changed .
# vit(id="ID", occasion= "Trial", score="Score", Data=Gardner.LD,
# group="Group",subset.ids=c(1, 4, 8, 13, 17, 21), col=c("Green", "Blue"))

# Now each individual specified is plotted seperately.
# vit(id="ID", occasion= "Trial", score="Score", Data=Gardner.LD,
# group="Group",subset.ids=c(1, 4, 8, 13, 17, 21), col=c("Green", "Blue"),
# All.in.One=FALSE)

```

vit.fitted

Visualize individual trajectories with fitted curve and quality of fit

Description

A function to help visualize individual trajectories in a longitudinal (i.e., analysis of change) context with fitted curve and quality of fit after analyzing the data with lme, lmer, or nlme function.

Usage

```

vit.fitted(fit.Model, layout = c(3, 3), ylab = "", xlab = "",
pct.rand = NULL, number.rand = NULL, subset.ids = NULL,
same.scales = TRUE, save.pdf = FALSE, save.eps = FALSE,
save.jpg = FALSE, file = "", ...)

```

Arguments

fit.Model	lme, nlme object produced by nlme package or lmer object produced by lme4 package
layout	define the per-page layout when All.in.One==FALSE
ylab	label for the ordinate (i.e., y-axis; see par)
xlab	label for the abscissa (i.e., x-axis; see par)
pct.rand	percentage of random trajectories to be plotted
number.rand	number of random trajectories to be plotted
subset.ids	id values for a selected subset of individuals to be plotted
same.scales	should the y-axes have the same scales

save.pdf	save a pdf file
save.eps	save a postscript file
save.jpg	save a jpg file
file	file name and file path for the graph(s) to save, if file="" a file would be saved in the current working directory
...	optional plotting specifications

Details

This function use the fitted model from nlme and lme functions in nlme package, and lmer function in lme4 package. It returns a set of plots of individual observed data, the fitted curves and the quality of fit.

Author(s)

Ken Kelley (University of Notre Dame; <KKelley@ND.Edu>) and Po-Ju Wu (Indiana University; <pojwu@indiana.edu>)

Examples

```
# Note that the following example works fine in R (<2.7.0), but not in
# the development version of R-2.7.0 (the cause can be either in this
# function or in the R program)

# data(Gardner.LD)
# library(nlme)
# Full.grouped.Gardner.LD <- groupedData(Score ~ Trial|ID, data=Gardner.LD, order.groups=FALSE)

# Examination of the plot reveals that the logistic change model does not adequately describe
# the trajectories of individuals 6 and 19 (a negative exponential change model would be
# more appropriate). Thus we remove these two subjects.
# grouped.Gardner.LD <- Full.grouped.Gardner.LD[!(Full.grouped.Gardner.LD["ID"]==6 |
#   Full.grouped.Gardner.LD["ID"]==19),]

# G.L.nlsList<- nlsList(SSlogis,grouped.Gardner.LD)
# G.L.nlme <- nlme(G.L.nlsList)
# to visualize individual trajectories: vit.fitted(G.L.nlme)
# plot 50 percent random trajectories: vit.fitted(G.L.nlme, pct.rand = 50)
```
